ID2212 Network Programming with Java Lecture 5

Java I/O. Overview of New I/O (NIO)

Leif Lindbäck, Vladimir Vlassov KTH/ICT/SCS HT 2015

Outline

- Java I/O
 - I/O using Streams
 - Types of streams
 - Standard streams
 - Accessing files
 - File channels
- Overview of New I/O
 - Buffers
 - Channels
 - Selectors

I/O in Java

- Package java.io
- I/O sources and destinations:
 - standard input, standard output, standard err
 - Files, streams of TCP socket and URL connections
- Input and output streams
 - Java provides different types of stream APIs, e.g. byte streams, character streams, object streams, etc.
 - Different stream reading and writing primitives, e.g. read/write, print
 - Basic streams: byte streams
 - Other streams are built on top of byte streams

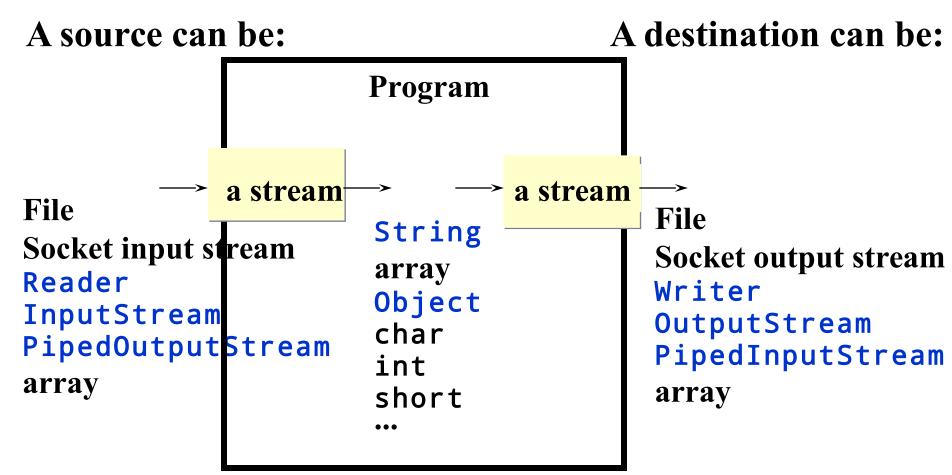

I/O in Java (cont'd)

```
• For example:
  try (BufferedReader r = new BufferedReader(
                        new InputStreamReader(
                        socket.getInputStream())) {
     String str;
     while ((str = r.readLine()) != null) {
       //process the line read
     }
   } catch (IOException e) {
     e.printStackTrace();
   }
```

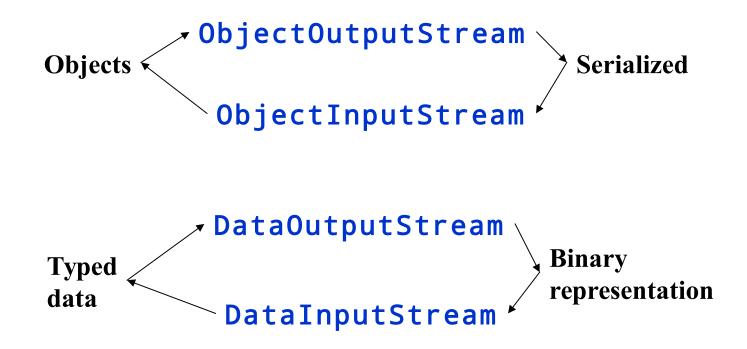

Streams

- *Streams* pass data from/to programs.
 - Input can be performed by different types of input streams, e.g. byte input stream, character input stream (reader)
 - Output can be performed by different types of output streams, e.g. byte output stream, character output stream (writer)
 - If a stream handles characters on the program side, then it is called a *reader* or a *writer*.

Streams

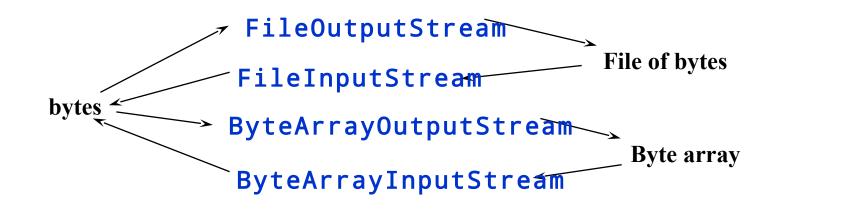

Some Types of Streams

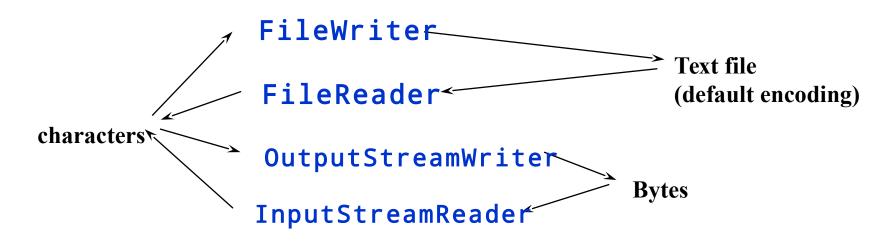

DataInputStream Example

```
try (DataInputStream inData = new DataInputStream(
                               new FileInputStream(
                               fileName))) {
 while (true) {
    no = inData.readInt();
    System.out.println("No " + no);
  }
} catch (EOFException done) {
} catch (FileNotFoundException e) {
  System.err.println("file " + fileName +
                      " is mising");
} catch (IOException e) {
  e.printStackTrace();
}
```

Types of Streams (cont'd)

Lecture 5: Java I/O. Overview of New I/O

Standard Streams

- Static fields in the java.lang.System class:
 - public static final PrintStream err;
 - The "standard" error output stream;
 - public static final PrintStream out;
 - The "standard" output stream;
 - public static final InputStream in;
 - The "standard" input stream.
 - All the streams are already open and ready to supply/accept data

System.out.println("your output " + result);

Files (java.io package)

- File class supports platform-independent usage of file- and directory names.
 - Instances of this class represent the name of a file or a directory on the host file system.
- Some constructors:

```
File(String path)
File(String dir, String fileName)
File(File dir, String fileName)
```

```
• Some interesting methods of File:
```

```
public boolean exists();
public boolean isDirectory();
public boolean isFile();
public long length();
public String[] list();
public String[] list(FileNameFilter f);
public boolean mkdir();
public boolean renameTo(File dest);
public boolean createNewFile()
```

File Streams

- Used to access files (for reading and writing) as a continues stream of bytes or characters
- FileInputStream and FileOutputStream
 - for reading and writing bytes to the file
- FileReader and FileWriter
 - for reading and writing character files
- Provide read and write methods
- Can be created by constructors given a file name or an object of File

FileInputStream inf = new FileInputStream(filename);

File Descriptor

- FileDescriptor class is a platform-independent representation of a handle of an open file or an open socket.
- Objects of this class
 - are returned by getFD() of FileInputStream, FileOutputStream, RandomAcessFile, ...
 - passed to (used by) FileInputStream,
 FileOutputStream, FileReader, FileWriter, ...

Random Access File

- **RandomAccessFile** class provides an API similar to the file API in C
 - Instances of this class represent the file opened in a given mode, e.g.
 - "r" for reading only
 - "rw" for reading and writing
 - Methods of this class provide means for reading from file, writing into file and changing current file access position.
 - All methods (including constructors) of this class may throw IOException.
 - Contains object of the FileDescriptor class as a handle of the file.

An Overview of New I/O

Use of the new I/O API when performing course programming assignments is optional

<u>New I/0 (java.nio.*..)</u>

- New I/O APIs introduced in JDK v 1.4
- NIO APIs supplements java.io
 - provides a new I/O model based on channels, buffers and selectors
 - enables non-blocking scalable I/O
 - allows improving performance of distributed applications (mostly for the server side)

Features in NIO APIs

- **Buffers** for data of primitive types, e.g. char, int
- *Channels*, a new primitive I/O abstraction
- *A multiplexed, non-blocking I/O facility* (selectors, selection keys, selectable channels) for writing scalable servers
- Character-set encoders and decoders
- A pattern-matching facility based on Perl-style regular expressions (java.util)
- A file interface that supports locks and memory mapping

NIO Packages

java.nio	Buffers, which are used throughout the NIO APIs.	
java.nio.channels	Channels and selectors.	
java.nio.charset	Character encodings.	
java.nio.channels. spi	Service-provider classes for channels.	
java.nio.charset.s pi	Service-provider classes for charsets.	
java.util.regex	Classes for matching character sequences against patterns specified by regular expressions.	

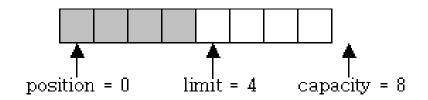

NIO Programming Abstractions

• Buffers

- Containers for data
- Can be filled, drained, flipped, rewind, etc.
- Can be written/read to/from a channel
- Channels of various types
 - Represent connections to entities capable of performing I/O operations, e.g. pipes, files and sockets
 - Can be selected when ready to perform I/O operation
- Selectors and selection keys
 - together with selectable channels define a multiplexed, non-blocking I/O facility. Used to select channels ready for I/O
- *Charsets* and their associated *decoders* and *encoders*
 - translate between bytes and Unicode characters

Buffers

- *Buffer* is a container for a fixed amount of data of a specific primitive type; Used by channels
 - Content, data
 - Capacity, size of buffer; set when the buffer is created; cannot be changed
 - Limit, the index of the first element that should not be read or written; limit ≤ capacity
 - Position, the index of the next element to be read or written
 - Mark, the index to which its position will be reset when the reset method is invoked
 - Buffer invariant: $0 \le mark \le position \le limit \le capacity$

Lecture 5: Java I/O. Overview of New I/O

Buffer Classes

Buffer	Superclass for other buffers; clear, flip, rewind, mark/reset
ByteBuffer	provides views as other buffers, e.g. IntBuffer get/put, compact, views; allocate, wrap
MappedByteBuffer	Subclass of the ByteBuffer A byte buffer mapped to a file
CharBuffer DoubleBuffer FloatBuffer IntBuffer LongBuffer	absolute (index-based) and relative (position-based) get/put, compact, allocate, wrap

Some Buffer's methods

<pre>static allocateDirect()</pre>	Allocates a new direct byte buffer. With direct ByteBuffer , JVM avoid intermediate buffering when performing native I/O operations directly upon the direct buffer.
<pre>static allocate()</pre>	allocate a buffer of a given capacity
clear()	clear the buffer, i.e. prepare the buffer for writing data into it by channel-reads or relative puts (limit = capacity; position = 0)
<pre>flip()</pre>	prepare the buffer for reading data from it by channel-writes or relative gets (limit = position; position = 0)
rewind()	prepare the buffer for re-reading data from it (position = 0)
mark()	set this buffer's mark at its position (mark = position)
reset()	reset this buffer's position to the previously-marked position (position = mark)

Some Buffer's methods (cont'd)

<pre>static wrap()</pre>	wrap a given array into a buffer; returns the buffer.
get/put	absolute (index-based) and relative (position-based) get/put data from/into the buffer; position = position -/+ 1;
asIntBuffer() asCharBuffer() …	create a view of this byte buffer as a other primitive type buffer, e.g. as an IntBuffer, as a CharBuffer, etc.
<pre>slice()</pre>	create a new buffer that shares part of this buffer's content starting at this buffer's position.
<pre>duplicate()</pre>	creates a new byte buffer that shares the this buffer's content.
<pre>compact()</pre>	copy data between position and limit to the beginning of the buffer; position is set to the number of data items copied.
<pre>boolean hasRemaining()</pre>	check whether there are any elements between the current position and the limit.

Creating Buffers

- Allocation
 - Create an empty buffer on top of a backing Java array Bytebuffer buf1 = ByteBuffer.allocate(100); IntBuffer buf2 = intBuffer.allocate(100);
- Direct allocation (only ByteBuffer)
 - Direct buffers (using DMA)
 ByteBuffer buf3 =
 ByteBuffer.allocateDirect(100);
- Wrapping
 - Wrap a buffer around existing data array
 byte[] data = "Some data".getBytes("UTF-8");
 ByteBuffer buf4 = ByteBuffer.wrap(data);
 char[] text = "Some text".toCharArray();
 CharBuffer buf5 = CharBuffer.wrap(text);

Filling/Draining Buffers

• Filling using wrap or put

```
String s = "Some String";
CharBuffer buf1 = CharBuffer.wrap(s);
CharBuffer buf2 = CharBuffer.allocate(s.length());
// put reversed s in to buf2
for (int i = s.length() - 1; i >= 0; i--) {
    buf2.put(s.charAt(i)); // relative put
} // position in buf2 should be 11 after the loop
```

• Draining using get

```
buf2.flip(); // limit = position; position = 0
String r = "";
while (buf2.hasRemaining())
    r += buf2.get();
}
```

Reading/Writing Buffers from/to <u>Channels</u>

• Reading from a channel to a buffer

```
while (buf.hasRemaining() &&
    channel.read(buf) != -1) {
    // process the buffer's content
}
```

• Writing to a channel from a buffer

```
while (buf.hasRemaining() &&
    channel.write(buf) != -1) ;
```

Channels

- *Channels* represent connections to various I/O sources, such as pipes, sockets, files, datagrams;
 - operate with buffers and I/O sources: move (read/write) data blocks into / out of buffers from / to the I/O sources;
 - can be open or closed;
 - can be blocking/non-blocking, selectable (socket, pipe), interruptible (file);
 - enable non-blocking I/O operations

Channels versus Streams

Channels (new I/O)	Streams (traditional I/O)
Write/read data to/from buffers; similar to buffered streams; buffers can be directly allocated in memory – efficient implementation	Write data onto output streams and reading data from input streams
Block-based: a streams of blocks from/to buffers	Byte-based: a continues stream of bytes
Bi-directional: tend to support both reading and writing on the same object (source, buffer)	Uni-directional: input streams and output streams

Some Channel Classes

- For TCP connections
 - SocketChannel
 - ServerSocketChannel
- For UDP communication
 - DatagramChannel
- For file access
 - FileChannel

FileChannel

- java.nio.channels.FileChannel
 - A channel for reading, writing, mapping, and manipulating a file.
 - Similar to RandomAccessFile
- Can be mapped to a buffer in the main memory
 - MappedByteBuffer()
- Has a current position within its file which can be both queried and modified.
- The file itself contains a variable-length sequence of bytes that can be read and written and whose current size can be queried.

Some methods of FileChannel

<pre>read (dst, pos) write (src, pos)</pre>	Read or write at an absolute position in a file without affecting the channel's position.
MappedByteBuffer()	Map a region of a file directly into memory.
force()	Force out file updates to the underlying storage device, in order to ensure that data are not lost in the event of a system crash.
<pre>transferTo() transferFrom()</pre>	Bytes can be transferred from a file to some other channel, and vice versa, in a way that can be optimized by many OSs into a very fast transfer directly to or from the file system cache.

FileChannel Example

```
import java.io.*;
import java.nio.*;
import java.nio.channels.*;
public class FileChannelTest {
  public static void main(String[] args) {
    String filename = (args.length > 0)? args[0] : "test.txt";
    try {
     FileInputStream inf = new FileInputStream(filename);
      FileChannel channel = inf.getChannel();
      MappedByteBuffer buffer =
          channel.map(FileChannel.MapMode.READ_ONLY,
                      0, channel.size());
     WritableByteChannel out = Channels.newChannel(System.out);
     while (buffer.hasRemaining() && out.write(buffer) != -1) {
        System.out.println("Writing the file " + filename);
      }
      channel.close();
    } catch (IOException e) {
      e.printStackTrace();
      System.exit(0);
    }
 }
```

Using transfer method

```
import java.io.*;
import java.nio.channels.*;
public class FileTransferTest {
  public static void main(String[] args) {
    String srcname = (args.length > 0)? args[0] : "test.txt";
    try {
      FileInputStream inf = new FileInputStream(srcname);
      FileChannel src = inf.getChannel();
      WritableByteChannel dst = Channels.newChannel(System.out);
      src.transferTo(0, src.size(), dst);
    } catch (IOException e) {
      e.printStackTrace();
      System.exit(0);
    }
}
```

<u>SocketChannel</u>

- A selectable channel for stream-oriented connecting sockets.
 - Reads from and writes to a TCP socket.
 - Uses ByteBuffer for reading and writing
 - Does not have public constructors
- Each SocketChannel is associated with a peer Socket object
 - Binding, closing, and manipulation of socket options must be done through the associated Socket object

SocketChannel Example 1

```
import java.io.IOException;
import java.nio.channels.*;
import java.net.*;
public class ChannelTest {
  public static void main(String[] args) {
    String host = (args.length > 0)? args[0] : "www.sun.com";
    int port = (args.length > 1) ? Integer.parseInt(args[1]) : 80;
    try {
      SocketChannel channel = SocketChannel.open();
      channel.configureBlocking(false);
      channel.connect(new InetSocketAddress(host, port));
      //can do something here while connecting
      while (!channel.finishConnect()) {
        System.out.println("Connecting to " + host + " on port " + port);
        // can do something here while connecting
      }
      System.out.println("Connected to " + host + " on port " + port);
      // communication with the server via channel
      channel.close();
    } catch (IOException e) {
      e.printStackTrace();
      System.exit(0);
    }
```

}

```
import java.io.IOException;
import java.nio.*;
                                              Example 2
import java.nio.channels.*;
import java.net.*;
public class HTTPClient {
 public static final String GET_REQUEST = "GET /index.html HTTP/1.0\n\n";
 public static void main(String[] args) {
    String host = (args.length > 0) ? args[0] : "www.sun.com";
    int port = (args.length > 1) ? Integer.parseInt(args[1]) : 80;
   WritableByteChannel out = Channels.newChannel(System.out);
   try {
     SocketChannel channel = SocketChannel.open(new InetSocketAddress()
                                                 host, port));
     ByteBuffer buf = ByteBuffer.wrap(GET_REQUEST.getBytes());
      channel.write(buf);
      buf = ByteBuffer.allocate(1024);
     while (buf.hasRemaining() && channel.read(buf) != -1) {
        buf.flip();
       out.write(buf);
       buf.clear();
      }
    } catch (IOException e) {
      e.printStackTrace();
      System.exit(0);
   }
  }
```

<u>ServerSocketChannel</u>

- A selectable channel for stream-oriented listening sockets.
 - Abstraction for listening network sockets.
 - Listens to a port for TCP connections.
 - Does not have public constructors
- Each ServerSocketChannel is associated with a peer ServerSocket object
 - Binding and the manipulation of socket options must be done through the associated ServerSocket object;

 accept on a ready ServerSocketChannel returns SocketChannel ServerSocketChannel serverChannel = ServerSocketChannel.open(); ServerSocket socket = serverChannel.socket(); socket.bind(new InetSocketAddress(port)); serverChannel.configureBlocking(false); selector = Selector.open(); serverChannel.register(selector, SelectionKey.OP_ACCEPT);

Selectors

- *Selector* is an object used to select a channel ready to communicate (to perform an operation)
 - Used to operate with several non-blocking channels
 - Allows readiness selection
 - Ability to choose a selectable channel that is ready for some of network operation, e.g. accept, write, read, connect

Selectable Channels

- Selectable channels include:
 - DatagramChannel
 - Pipe.SinkChannel
 - Pipe.SourceChannel
 - ServerSocketChannel
 - SocketChannel
- Channels are registered with a selector for specific operations, e.g. accept, read, write
- Registration is represented by a *selection key*

Selection Keys

- A selector operates with set of selection keys
- *Selection key* is a token representing the registration of a channel with a selector
- The selector maintains three sets of keys
 - *Key set* contains the keys with registered channels;
 - Selected-key set contains the keys with channels ready for at least one of the operations;
 - *Cancelled-key set* contains cancelled keys whose channels have not yet been deregistered.
 - The last two sets are sub-sets of the Key set.

Use of Selectors

- Create a selector Selector selector = Selector.open();
- Configure a channel to be non-blocking channel.configureBlocking(false);
- Register a channel with the selector for specified operations (accept, connect, read, write) ServerSocketChannel serverChannel = ServerSocketChannel.open(); ServerSocket serverSocket = serverChannel.socket(); serverSocket.bind(new InetSocketAddress(port)); serverChannel.configureBlocking(false); serverChannel.register(selector, SelectionKey.OP_ACCEPT);
 - Register as many channels as you have/need

Use of Selectors (cont'd)

- Select() on the selector to perform the selection of keys with ready channels
 - Selects a set of keys whose channels are ready for I/O.
- selectNow() non-blocking select: returns zero if no channels are ready
- **selectedKeys()** on the selector to get the selected-key set
- Iterate over the selected-key set and handle the channels ready for different I/O operations, e.g. read, write, accept

Lecture 5: Java I/O. Overview of New I/O

<u>SelectionKey</u>

• Upon registration, each of the registered channels is assigned a selection key.

```
SelectionKey clientKey =
   clientChannel.register(selector,
     SelectionKey.OP_READ | SelectionKey.OP_WRITE);
```

• Selection key allows attaching of a single arbitrary object to it

Associate application data (e.g. buffer, state) with the key (channel)
 ByteBuffer buffer = ByteBuffer.allocate(1024);
 clientKey.attach(buffer);

 Get the channel and attachment from the key SocketChannel clientChannel = (SocketChannel) key.channel(); ByteBuffer buffer = (ByteBuffer) key.attachment(); Lecture 5: Java I/O. Overview of New I/O

Non-Blocking Server

```
while (true) {
  selector.select();
  Iterator<SelectionKey> keys = selector.selectedKeys().iterator();
 while (keys.hasNext()) {
    SelectionKey key = keys.next();
    keys.remove();
    if (key.isAcceptable()) { // accept connection.
      ServerSocketChannel server =
          (ServerSocketChannel) key.channel();
      SocketChannel channel = server.accept();
      channel.configureBlocking(false);
      channel.register(selector, SelectionKey.OP_READ,
                       ByteBuffer.allocate(1024));
    } else if (key.isReadable()) { // read from a channel.
      SocketChannel channel = (SocketChannel) key.channel();
      ByteBuffer buffer = (ByteBuffer) key.attachment();
      channel.read(buffer);
      key.interestOps(SelectionKey.OP_READ | SelectionKey.OP_WRITE);
```

Non-Blocking Server, Cont'd

```
} else if (key.isWritable()) { // write buffer to channel.
  SocketChannel channel = (SocketChannel) key.channel();
  ByteBuffer buffer = (ByteBuffer) key.attachment();
  buffer.flip();
  channel.write(buffer);
  if (buffer.hasRemaining()) {
    buffer.compact();
  } else {
    buffer.clear();
  }
  key.interestOps(SelectionKey.OP_READ);
}
```

}
