

# Sentiment, stance and applications of distributional semantics

Maria Skeppstedt

# Sentiment, stance and applications of distributional semantics

# Sentiment analysis (opinion mining)

- Aims at determining the attitude of the speaker/writer
  - \* In a chunk of text (e.g., a document or sentence)
  - \* Towards a certain topic
- Categories:
  - \* Positive, negative, (neutral)
  - \* More detailed

# Movie reviews

- Excruciatingly unfunny and pitifully unromantic.
- The picture emerges as a surprisingly anemic disappointment.
- A sensitive, insightful and beautifully rendered film.
- The spark of special anime magic here is unmistakable and hard to resist.
- Maybe you'll be lucky , and there'll be a power outage during your screening so you can get your money back.

# Methods for sentiment analysis

- Train a machine learning classifier
- Use lexicon and rules
- (or combine the methods)

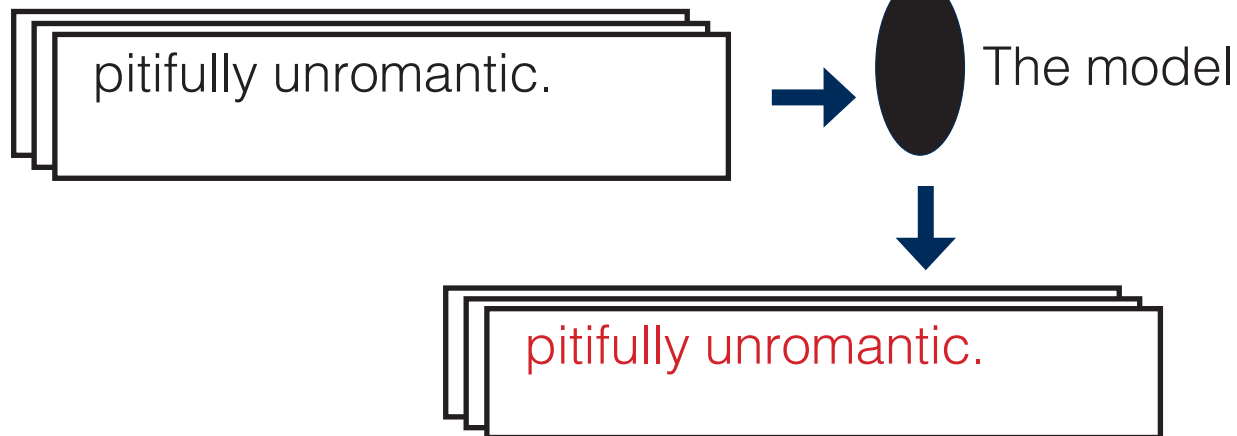

# Train a machine learning classifier

Annotating text and training the model

Applying the model

# Examples of machine learning Frameworks

- Scikit-learn
- NLTK (natural language toolkit)
- CRF++

# Methods for sentiment analysis

- Train a machine learning classifier
  - \* See for instance Socher et al. (2013) that classified English movie review sentences into positive and negative sentiment.
  - \* Trained their classifier on 11,855 manually labelled sentences.

(R. Socher, A. Perelygin, J. Wu, J. Chuang, C. D. Manning, A. Y. Ng, C. Potts, Recursive deep models for semantic compositionality over a sentiment treebank)

# Methods based on lexicons and rules

- Lexicons for different polarities
- Sometimes with different strength on the words
  - \* Does not need the large amount of training data that is typically required for machine learning methods
  - \* More flexible  
(e.g, to add new sentiment poles and new languages)

# Commercial use of sentiment analysis

I want to retrieve everything positive and negative that is said about the products I sell.

- My Dad absolutely loved these. Solved his problem of canes being propped against furniture only to fall over.
- Holder works fine. The product description is lacking a photo of the other side. The holder is open on the back side. This is how you attach it to the cane.

# Also looking at the big picture (data aggregated from many authors)

When it is not a good time to emphasise on the Russian market that your products are made in Sweden.

## WHAT PEOPLE THINK ABOUT SWEDEN IN RUSSIAN

Negative Positive Violence Skeptical

# Also, aggregated sentiment on e.g., political issues

**HILLARY CLINTON**   
 Occurrence 4808 mentions  
 Time April 13  
 18% more negative than positive  
 NEW YORK (AP) " Presidential candidate Hillary Clinton ...

**TED CRUZ**

 Time April 13  
 38% more negative than positive  
 Fox says its anchor, Megyn Kelly, met Wednesday with Re...

# Gavagai monitor

- The two previous examples showed Gavagai monitor
- Different targets
  - \* Sweden
  - \* Hillary Clinton, Ted Cruz ..
- Several sentiment poles (called tonality):
  - \* Positive, negative, violence, skeptical

### FORMER WHITE HOUSE GARDENER SELLING HILLARY CLINTON'S CAR

- In an April 6, 2016 photo, Gettysburg, Pa. resident Mike Lawn holds up the title to Hillary Clinton's 1986 Oldsmobile Cutlass, with Clinton's signature, in Gettysburg, Pa. The retired White House gardener is selling Clinton's 1986 Oldsmobile Cutlass, which he bought at an auction for the residence's workers and has been sitting in his Pennsylvania garage for years.
- The title still reads "Hillary Rodham Clinton" because Lawn never got the vehicle re-tagged.

# Sentiment, stance and applications of distributional semantics

# Stance detection

- Position on an issue.
- E.g. SemEval-2106 shared task: ‘In favour’, ‘against’ or ‘none of these’ towards a target.
  - \* Target e.g., ‘Climate Change is a Real Concern’
  - \* ‘In favour’ and ‘against’ not the same as ‘positive’ and ‘negative’ sentiment. E.g. ‘I believe global warming has mostly positive effects’. (‘positive’ and ‘against’)

<http://alt.qcri.org/semeval2016/task6/>

# Language components used when expressing stance

The StaViCTA project at Linnaeus University. A collaboration between Gavagai and researchers at Lund and Linnaeus University.

- Sentiment (**A** is good) (**B** is bad)
- Uncertainty (**A** might be true)
- Contrast (I believe **A**, but I do not believe **B**)
- Hypothetical (If **A** then **B** would happen)
- Agreement/disagreement (I can't agree on **A** )

# Used methods for detecting stance components

- Manually annotate a lot of text to train a machine learning classifier
  - \* Takes a lot of time
  - \* Boring
- Possible solution 1: Use lexicons and rules instead of machine learning
- Possible solution 2: Use active learning

# Active learning

- The standard method is to randomly select training data for the classifier
- When active learning is used, there are different methods for selecting good training samples
  - \* I.e., training samples that are useful for the classifier.

# Sentiment, stance and applications of distributional semantics

# Distributional semantics

Recap from a previous lecture  
(about Random Indexing)

- Expressions that occur in similar context tend to have a similar meaning.

(The distributional hypothesis.)

- \* 'I usually have a cup of coffee in the morning'
- \* 'I usually have a cup of tea in the evening'
- \* 'I drink too much coffee'
- \* 'It's better to drink tea in the evening'

# Represent distributional semantics with a vector space

- \* I usually have a cup of **coffee** in the morning
- \* I usually have a cup of **tea** in the evening

## Context vectors

	cup	morning	evening	...
<b>coffee</b>	[1	1	0	]
<b>tea</b>	[1	0	1	...]
<b>term_1</b>	[0	0	0	20 ...
...				
<b>term_n</b>	[0	0	0	2 ... ]

\* The context vectors represent the context in which a term has occurred.

\* Here, a context window of 1+1 (removed stop words).

# The vector space model

A geometrical metaphor for meaning. Similarity of two terms are measured by the distance between their vectors.

# Methods for building this vector space

A number of different methods for creating the models. Typically represent the the vector space with smaller matrixes. Examples are:

- Random indexing
- Word2vec

A new word for vector spaces are word embeddings.

See the following blog post <http://www.gavagai.se/blog/2015/09/30/a-brief-history-of-word-embeddings/>
