# Interactive Theorem Proving (ITP) Course

Thomas Tuerk (tuerk@kth.se)

Academic Year 2016/17, Period 4

version d3875e1 of Mon. Jun 5 16:28:23 2017

# Part I

# Introduction

#### Motivation

- Complex systems almost certainly contain bugs.
- Critical systems (e. g. avionics) need to meet very high standards.
- It is infeasible in practice to achieve such high standards just by testing.
- Debugging via testing suffers from diminishing returns.

"Program testing can be used to show the presence of bugs, but never to show their absence!"

— Edsger W. Dijkstra

## Famous Bugs

- Pentium FDIV bug (1994)
   (missing entry in lookup table, \$475 million damage)
- Ariane V explosion (1996) (integer overflow, \$1 billion prototype destroyed)
- Mars Climate Orbiter (1999)
   (destroyed in Mars orbit, mixup of units pound-force and newtons)
- Knight Capital Group Error in Ultra Short Time Trading (2012) (faulty deployment, repurposing of critical flag, \$440 lost in 45 min on stock exchange)
- . . .

#### Fun to read

http://www.cs.tau.ac.il/~nachumd/verify/horror.html https://en.wikipedia.org/wiki/List\_of\_software\_bugs

### Proof

- proof can show absence of errors in design
- but proofs talk about a design, not a real system
- ullet  $\Rightarrow$  testing and proving complement each other

"As far as the laws of mathematics refer to reality, they are not certain; and as far as they are certain, they do not refer to reality."

— Albert Einstein

←□ → ←□ → ← □ → ← □ → へ○

#### Mathematical vs. Formal Proof

#### Mathematical Proof

- informal, convince other mathematicians
- checked by community of domain experts
- subtle errors are hard to find
- often provide some new insight about our world
- often short, but require creativity and a brilliant idea

#### Formal Proof

- formal, rigorously use a logical formalism
- checkable by stupid machines
- very reliable
- often contain no new ideas and no amazing insights
- often long, very tedious, but largely trivial

We are interested in formal proofs in this lecture.

#### Detail Level of Formal Proof

In **Principia Mathematica** it takes 300 pages to prove 1+1=2.

This is nicely illustrated in Logicomix - An Epic Search for Truth.

# Automated vs Manual (Formal) Proof

### Fully Manual Proof

- very tedious one has to grind through many trivial but detailed proofs
- easy to make mistakes
- hard to keep track of all assumptions and preconditions
- hard to maintain, if something changes (see Ariane V)

#### **Automated Proof**

- amazing success in certain areas
- but still often infeasible for interesting problems
- hard to get insights in case a proof attempt fails
- even if it works, it is often not that automated
  - run automated tool for a few days
  - abort, change command line arguments to use different heuristics
  - run again and iterate till you find a set of heuristics that prove it fully automatically in a few seconds

#### Interactive Proofs

- combine strengths of manual and automated proofs
- many different options to combine automated and manual proofs
  - ▶ mainly check existing proofs (e.g. HOL Zero)
  - user mainly provides lemmata statements, computer searches proofs using previous lemmata and very few hints (e. g. ACL 2)
  - most systems are somewhere in the middle
- typically the human user
  - provides insights into the problem
  - structures the proof
  - provides main arguments
- typically the computer
  - checks proof
  - keeps track of all use assumptions
  - provides automation to grind through lengthy, but trivial proofs

## Typical Interactive Proof Activities

- provide precise definitions of concepts
- state properties of these concepts
- prove these properties
  - human provides insight and structure
  - computer does book-keeping and automates simple proofs
- build and use libraries of formal definitions and proofs
  - formalisations of mathematical theories like
    - ★ lists, sets, bags, . . .
    - ★ real numbers
    - ★ probability theory
  - specifications of real-world artefacts like
    - processors
    - ★ programming languages
    - network protocols
  - reasoning tools

There is a strong connection with programming. Lessons learned in Software Engineering apply.

#### Different Interactive Provers

- there are many different interactive provers, e.g.
  - ► Isabelle/HOL
  - Coq
  - PVS
  - HOL family of provers
  - ► ACL2
  - **•** . . .
- important differences
  - the formalism used
  - level of trustworthiness
  - level of automation
  - libraries
  - languages for writing proofs
  - user interface
  - **.** . . .

## Which theorem prover is the best one? :-)

- there is no best theorem prover
- better question: Which is the best one for a certain purpose?
- important points to consider
  - existing libraries
  - used logic
  - level of automation
  - user interface
  - importance development speed versus trustworthiness
  - How familiar are you with the different provers?
  - Which prover do people in your vicinity use?
  - your personal preferences
  - **.** . . .

In this course we use the HOL theorem prover, because it is used by the TCS group.

# Part II

# Organisational Matters

#### Aims of this Course

#### Aims

- introduction to interactive theorem proving (ITP)
- being able to evaluate whether a problem can benefit from ITP
- hands-on experience with HOL
- learn how to build a formal model
- learn how to express and prove important properties of such a model
- learn about basic conformance testing
- use a theorem prover on a small project

#### Required Prerequisites

- some experience with functional programming
- knowing Standard ML syntax
- basic knowledge about logic (e. g. First Order Logic)

#### Dates

- Interactive Theorem Proving Course takes place in Period 4 of the academic year 2016/2017
- always in room 4523 or 4532
- each week

```
Mondays 10:15 - 11:45 lecture
Wednesdays 10:00 - 12:00 practical session
Fridays 13:00 - 15:00 practical session
```

- no lecture on Monday, 1st of May, instead on Wednesday, 3rd May
- last lecture: 12th of June
- last practical session: 21st of June
- 9 lectures, 17 practical sessions

#### Exercises

- after each lecture an exercise sheet is handed out
- work on these exercises alone, except if stated otherwise explicitly
- exercise sheet contains due date
  - usually 10 days time to work on it
  - hand in during practical sessions
  - lacktriangle lecture Monday  $\longrightarrow$  hand in at latest in next week's Friday session
- main purpose: understanding ITP and learn how to use HOL
  - no detailed grading, just pass/fail
  - retries possible till pass
  - if stuck, ask me or one another
  - practical sessions intend to provide this opportunity

#### Practical Sessions

- very informal
- main purpose: work on exercises
  - I have a look and provide feedback
  - you can ask questions
  - I might sometimes explain things not covered in the lectures
  - ▶ I might provide some concrete tips and tricks
  - you can also discuss with each other
- attendance not required, but highly recommended
  - exception: session on 21st April
- only requirement: turn up long enough to hand in exercises
- you need to bring your own computer

### Handing-in Exercises

- exercises are intended to be handed-in during practical sessions
- attend at least one practical session each week
- leave reasonable time to discuss exercises
  - don't try to hand your solution in Friday 14:55
- retries possible, but reasonable attempt before deadline required
- handing-in outside practical sessions
  - only if you have a good reason
  - decided on a case-by-case basis
- electronic hand-ins
  - only to get detailed feedback
  - does not replace personal hand-in
  - exceptions on a case-by-case basis if there is a good reason
  - I recommend using a KTH GitHub repo

## Passing the ITP Course

- there is only a pass/fail mark
- to pass you need to
  - attend at least 7 of the 9 lectures
  - pass 8 of the 9 exercises

#### Communication

- we have the advantage of being a small group
- therefore we are flexible
- so please ask questions, even during lectures
- there are many shy people, therefore
  - anonymous checklist after each lecture
  - anonymous background questionnaire in first practical session
- further information is posted on Interactive Theorem Proving Course group on Group Web
- contact me (Thomas Tuerk) directly, e.g. via email thomas@kth.se

### Part III

# **HOL 4 History and Architecture**

# LCF - Logic of Computable Functions

- Standford LCF 1971-72 by Milner et al.
- formalism devised by Dana Scott in 1969
- intended to reason about recursively defined functions
- intended for computer science applications
- strengths
  - powerful simplification mechanism
  - support for backward proof
- limitations
  - proofs need a lot of memory
  - fixed, hard-coded set of proof commands

Robin Milner (1934 - 2010)

## LCF - Logic of Computable Functions II

- Milner worked on improving LCF in Edinburgh
- research assistants
  - Lockwood Morris
  - Malcolm Newey
  - Chris Wadsworth
  - Mike Gordon
- Edinburgh LCF 1979
- introduction of Meta Language (ML)
- ML was invented to write proof procedures
- ML become an influential functional programming language
- using ML allowed implementing the LCF approach

### LCF Approach

- implement an abstract datatype thm to represent theorems
- semantics of ML ensure that values of type thm can only be created using its interface
- interface is very small
  - predefined theorems are axioms
  - function with result type theorem are inferences
- → However you create a theorem, it is valid.
- together with similar abstract datatypes for types and terms, this forms the kernel

### LCF Approach II

### Modus Ponens Example

#### Inference Rule

$$\frac{\Gamma \vdash a \Rightarrow b \qquad \Delta \vdash a}{\Gamma \cup \Delta \vdash b}$$

#### **SML** function

val MP : thm -> thm -> thm MP(
$$\Gamma \vdash a \Rightarrow b$$
)( $\Delta \vdash a$ ) = ( $\Gamma \cup \Delta \vdash b$ )

- very trustworthy only the small kernel needs to be trusted
- efficient no need to store proofs

#### Easy to extend and automate

However complicated and potentially buggy your code is, if a value of type theorem is produced, it has been created through the small trusted interface. Therefore the statement really holds.

### LCF Style Systems

There are now many interactive theorem provers out there that use an approach similar to that of Edinburgh LCF.

- HOL family
  - ► HOL theorem prover
  - ► HOL Light
  - ▶ HOL Zero
  - Proof Power
  - **•** ...
- Isabelle
- Nuprl
- Coq
- . . .

### History of HOL

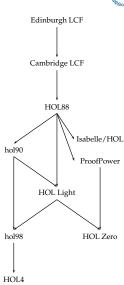

- 1979 Edinburgh LCF by Milner, Gordon, et al.
- 1981 Mike Gordon becomes lecturer in Cambridge
- 1985 Cambridge LCF
  - Larry Paulson and Gèrard Huet
  - implementation of ML compiler
  - powerful simplifier
  - various improvements and extensions
- 1988 HOL
  - Mike Gordon and Keith Hanna
  - adaption of Cambridge LCF to classical higher order logic
  - intention: hardware verification
- 1990 HOL90 reimplementation in SML by Konrad Slind at University of Calgary
- 1998 HOL98 implementation in Moscow ML and new library and theory mechanism
- since then HOL Kananaskis releases, called informally HOL 4

### Family of HOL

- ProofPower commercial version of HOL88 by Roger Jones, Rob Arthan et al.
- HOL Light
   lean CAML / OCaml port by John Harrison
- HOL Zero trustworthy proof checker by Mark Adams
- Isabelle
  - ▶ 1990 by Larry Paulson
  - meta-theorem prover that supports multiple logics
  - however, mainly HOL used, ZF a little
  - nowadays probably the most widely used HOL system
  - originally designed for software verification

# Part IV

# HOL's Logic

### **HOL** Logic

- the HOL theorem prover uses a version of classical higher order logic: classical higher order predicate calculus with terms from the typed lambda calculus (i.e. simple type theory)
- this sounds complicated, but is intuitive for SML programmers
- (S)ML and HOL logic designed to fit each other
- if you understand SML, you understand HOL logic

HOL = functional programming + logic

#### **Ambiguity Warning**

The acronym *HOL* refers to both the *HOL interactive theorem prover* and the *HOL logic* used by it. It's also a common abbreviation for *higher order logic* in general.

### **Types**

- SML datatype for types
  - ▶ Type Variables ('a,  $\alpha$ , 'b,  $\beta$ , ...) Type variables are implicitly universally quantified. Theorems containing type variables hold for all instantiations of these. Proofs using type variables can be seen as proof schemata.
  - Atomic Types (c) Atomic types denote fixed types. Examples: num, bool, unit
  - ▶ Compound Types  $((\sigma_1, \ldots, \sigma_n)op)$  op is a type operator of arity n and  $\sigma_1, \ldots, \sigma_n$  argument types. Type operators denote operations for constructing types. Examples: num list or 'a # 'b.
  - ▶ Function Types  $(\sigma_1 \to \sigma_2)$  $\sigma_1 \to \sigma_2$  is the type of total functions from  $\sigma_1$  to  $\sigma_2$ .
- types are never empty in HOL, i. e. for each type at least one value exists
- all HOL functions are total

#### **Terms**

- SML datatype for terms
  - ► Variables (x, y, ...)
  - ► Constants (c,...)
  - ► Function Application (f a)
  - ▶ Lambda Abstraction ( $\x$ . f x or  $\lambda x$ . fx) Lambda abstraction represents anonymous function definition. The corresponding SML syntax is fn x => f x.
- terms have to be well-typed
- same typing rules and same type-inference as in SML take place
- terms very similar to SML expressions
- notice: predicates are functions with return type bool, i.e. no distinction between functions and predicates, terms and formulae

### Terms II

HOL term	SML expression	type HOL / SML
0	0	num / int
x:'a	x:'a	variable of type 'a
x:bool	x:bool	variable of type bool
x + 5	x + 5	applying function + to $x$ and 5
$\x$ . x + 5	$fn x \Rightarrow x + 5$	anonymous (a. k. a. inline) function
		of type num -> num
(5, T)	(5, true)	<pre>num # bool / int * bool</pre>
[5;3;2]++[6]	[5,3,2]@[6]	<pre>num list / int list</pre>

## Free and Bound Variables / Alpha Equivalence

- in SML, the names of function arguments does not matter (much)
- similarly in HOL, the names of variables used by lambda-abstractions does not matter (much)
- the lambda-expression  $\lambda x$ . t is said to **bind** the variables x in term t
- variables that are guarded by a lambda expression are called bound
- all other variables are free
- Example: x is free and y is bound in  $(x = 5) \land (\lambda y. (y < x))$  3
- the names of bound variables are unimportant semantically
- two terms are called alpha-equivalent iff they differ only in the names of bound variables
- Example:  $\lambda x$ . x and  $\lambda y$ . y are alpha-equivalent
- Example: x and y are not alpha-equivalent

#### **Theorems**

- theorems are of the form  $\Gamma \vdash p$  where
  - Γ is a set of hypothesis
  - p is the conclusion of the theorem
  - $\blacktriangleright$  all elements of  $\Gamma$  and p are formulae, i. e. terms of type bool
- $\Gamma \vdash p$  records that using  $\Gamma$  the statement p has been proved
- notice difference to logic: there it means can be proved
- the proof itself is not recorded
- theorems can only be created through a small interface in the kernel

### **HOL Light Kernel**

- the HOL kernel is hard to explain
  - for historic reasons some concepts are represented rather complicated
  - for speed reasons some derivable concepts have been added
- instead consider the HOL Light kernel, which is a cleaned-up version
- there are two predefined constants

```
> = : 'a -> 'a -> bool
> @ : ('a -> bool) -> 'a
```

- there are two predefined types
  - ▶ bool
  - ▶ ind
- the meaning of these types and constants is given by inference rules and axioms

# HOL Light Inferences I

$$\frac{\Gamma \vdash s = t}{\Gamma \vdash t = t} \text{ REFL} \qquad \qquad \frac{\Gamma \vdash s = t}{\Gamma \vdash \lambda x. \ s = \lambda x. \ t} \text{ ABS}$$

$$\frac{\Delta \vdash t = u}{\Gamma \cup \Delta \vdash s = u} \text{ TRANS}$$

$$\frac{\Gamma \vdash s = t}{\Gamma \vdash \lambda x. \ s = \lambda x. \ t} \text{ BETA}$$

$$\frac{\Gamma \vdash s = t}{\Delta \vdash u = v}$$

$$\frac{\Delta \vdash u = v}{types \ fit}$$

$$\frac{\tau \vdash s = t}{\Gamma \cup \Delta \vdash s(u) = t(v)} \text{ COMB}$$

## HOL Light Inferences II

$$\frac{\Gamma \vdash \rho \Leftrightarrow q \qquad \Delta \vdash \rho}{\Gamma \cup \Delta \vdash q} \text{ EQ\_MP}$$

$$\frac{\Gamma \vdash p \qquad \Delta \vdash q}{(\Gamma - \{q\}) \cup (\Delta - \{p\}) \vdash \rho \Leftrightarrow q} \text{ DEDUCT\_ANTISYM\_RULE}$$

$$\frac{\Gamma[x_1, \dots, x_n] \vdash p[x_1, \dots, x_n]}{\Gamma[t_1, \dots, t_n] \vdash p[t_1, \dots, t_n]} \text{ INST}$$

$$\frac{\Gamma[\alpha_1, \dots, \alpha_n] \vdash p[\alpha_1, \dots, \alpha_n]}{\Gamma[\gamma_1, \dots, \gamma_n] \vdash p[\gamma_1, \dots, \gamma_n]} \text{ INST\_TYPE}$$

# **HOL Light Axioms and Definition Principles**

3 axioms needed

ETA\_AX 
$$|-(\lambda x. t x) = t$$
  
SELECT\_AX  $|-P x \Longrightarrow P((@)P))$   
INFINITY\_AX predefined type ind is infinite

- definition principle for constants
  - constants can be introduced as abbreviations
  - constraint: no free vars and no new type vars
- definition principle for types
  - new types can be defined as non-empty subtypes of existing types
- both principles
  - lead to conservative extensions
  - preserve consistency

# HOL Light derived concepts

Everything else is derived from this small kernel.

$$T =_{def} (\lambda p. p) = (\lambda p. p)$$

$$\wedge =_{def} \lambda p q. (\lambda f. f p q) = (\lambda f. f T T)$$

$$\implies =_{def} \lambda p q. (p \wedge q \Leftrightarrow p)$$

$$\forall =_{def} \lambda P. (P = \lambda x. T)$$

$$\exists =_{def} \lambda P. (\forall q. (\forall x. P(x) \Longrightarrow q) \Longrightarrow q)$$
...

### Multiple Kernels

- Kernel defines abstract datatypes for types, terms and theorems
- one does not need to look at the internal implementation
- therefore, easy to exchange
- there are at least 3 different kernels for HOL
  - standard kernel (de Bruijn indices)
  - experimental kernel (name / type pairs)
  - OpenTheory kernel (for proof recording)

# **HOL Logic Summary**

- HOL theorem prover uses classical higher order logic
- HOL logic is very similar to SML
  - syntax
    - type system
    - type inference
- HOL theorem prover very trustworthy because of LCF approach
  - there is a small kernel
  - proofs are not stored explicitly
- you don't need to know the details of the kernel
- usually one works at a much higher level of abstraction

# Part V

# Basic HOL Usage

## **HOL Technical Usage Issues**

- practical issues are discussed in practical sessions
  - how to install HOL
  - which key-combinations to use in emacs-mode
  - detailed signature of libraries and theories
  - all parameters and options of certain tools
  - **.** . . .
- exercise sheets sometimes
  - ask to read some documentation
  - provide examples
  - list references where to get additional information
- if you have problems, ask me outside lecture (tuerk@kth.se)
- covered only very briefly in lectures

## Installing HOL

- webpage: https://hol-theorem-prover.org
- HOL supports two SML implementations
  - Moscow ML (http://mosml.org)
  - PolyML (http://www.polyml.org)
- I recommend using PolyML
- please use emacs with
  - ▶ hol-mode
  - sml-mode
  - hol-unicode, if you want to type Unicode
- please install recent revision from git repo or Kananaskis 11 release
- documentation found on HOL webpage and with sources

### General Architecture

- HOL is a collection of SML modules
- starting HOL starts a SML Read-Eval-Print-Loop (REPL) with
  - some HOL modules loaded
  - some default modules opened
  - ▶ an input wrapper to help parsing terms called unquote
- unquote provides special quotes for terms and types
  - implemented as input filter
  - ''my-term'' becomes Parse.Term [QUOTE "my-term"]
  - ' ':my-type'' becomes Parse.Type [QUOTE ":my-type"]
- main interfaces
  - emacs (used in the course)
  - vim
  - bare shell

#### **Filenames**

- \*Script.sml HOL proof script file
  - script files contain definitions and proof scripts
  - executing them results in HOL searching and checking proofs
  - this might take very long
  - resulting theorems are stored in \*Theory.{sml|sig} files
- \*Theory. {sml|sig} HOL theory
  - auto-generated by corresponding script file
  - load quickly, because they don't search/check proofs
  - do not edit theory files
- \*Syntax.{sml|sig} syntax libraries
  - contain syntax related functions
  - i. e. functions to construct and destruct terms and types
- \*Lib.{sml|sig} general libraries
- \*Simps.{sml|sig} simplifications
- selftest.sml selftest for current directory

## **Directory Structure**

- bin HOL binaries
- src HOL sources
- examples HOL examples
  - interesting projects by various people
  - examples owned by their developer
  - coding style and level of maintenance differ a lot
- help sources for reference manual
  - after compilation home of reference HTML page
- Manual HOL manuals
  - Tutorial
  - Description
  - Reference (PDF version)
  - ▶ Interaction
  - Quick (cheat pages)
  - Style-guide

### Unicode

- HOL supports both Unicode and pure ASCII input and output
- advantages of Unicode compared to ASCII
  - easier to read (good fonts provided)
  - no need to learn special ASCII syntax
- disadvanges of Unicode compared to ASCII
  - harder to type (even with hol-unicode.el)
  - less portable between systems
- whether you like Unicode is highly a matter of personal taste
- HOL's policy
  - no Unicode in HOL's source directory src
  - Unicode in examples directory examples is fine
- I recommend turning Unicode output off initially
  - this simplifies learning the ASCII syntax
  - no need for special fonts
  - it is easier to copy and paste terms from HOL's output

### Where to find help?

- reference manual
  - available as HTML pages, single PDF file and in-system help
- description manual
- Style-guide (still under development)
- HOL webpage (https://hol-theorem-prover.org)
- mailing-list hol-info
- DB.match and DB.find
- \*Theory.sig and selftest.sml files
- ask someone, e.g. me :-) (tuerk@kth.se)

# Part VI

# Forward Proofs

### Kernel too detailed

- we already discussed the HOL Logic
- the kernel itself does not even contain basic logic operators
- usually one uses a much higher level of abstraction
  - many operations and datatypes are defined
  - high-level derived inference rules are used
- let's now look at this more common abstraction level

### Common Terms and Types

	Unicode	<b>ASCII</b>
type vars	$\alpha$ , $\beta$ ,	'a, 'b,
type annotated term	term:type	term:type
true	T	T
false	F	F
negation	¬b	~b
conjunction	b1 ∧ b2	b1 /\ b2
disjunction	b1 ∨ b2	b1 \/ b2
implication	$b1 \implies b2$	b1 ==> b2
equivalence	b1 ⇔ b2	b1 <=> b2
disequation	$v1 \neq v2$	v1 <> v2
all-quantification	$\forall x. P x$	!x. P x
existential quantification	$\exists x. P x$	?x. P x
Hilbert's choice operator	0x. P x	0x. P x

There are similar restrictions to constant and variable names as in SML. HOL specific: don't start variable names with an underscore

### Syntax conventions

- common function syntax
  - prefix notation, e.g. SUC x
  - ▶ infix notation, e.g. x + y
  - quantifier notation, e.g.  $\forall x$ . P x means  $(\forall)$   $(\lambda x$ . P x)
- infix and quantifier notation functions can turned into prefix notation Example: (+) x y and + x y are the same as x + y
- quantifiers of the same type don't need to be repeated Example: ∀x y. P x y is short for ∀x. ∀y. P x y
- there is special syntax for some functions
   Example: if c then v1 else v2 is nice syntax for COND c v1 v2
- associative infix operators are usually right-associative
   Example: b1 /\ b2 /\ b3 is parsed as b1 /\ (b2 /\ b3)

### Operator Precedence

It is easy to misjudge the binding strength of certain operators. Therefore use plenty of parenthesis.

### **Creating Terms**

### Term Parser

Use special quotation provided by unquote.

### **Use Syntax Functions**

Terms are just SML values of type term. You can use syntax functions (usually defined in \*Syntax.sml files) to create them.

### Creating Terms II

#### **Parser**

```
":bool"
CTCC
" ~ h " "
· · · · · / · · · · · ·
··· ... ==> ...··
```

### **Syntax Funs**

```
mk_type ("bool", []) or bool
mk_const ("T", bool) or T
mk_neg (
    mk_var ("b", bool))
mk_conj (..., ...)
mk_disj (..., ...)
mk_imp (..., ...)
mk_eq (..., ...)
mk_neg (mk_eq (..., ...))
```

type of Booleans term true negation of Boolean var b conjunction disjunction implication equation equivalence negated equation

# Inference Rules for Equality

$$\overline{\vdash t = t} \text{ REFL}$$

$$\Gamma \vdash s = t$$

$$x \text{ not free in } \Gamma$$

$$\overline{\Gamma \vdash \lambda x. \ s = \lambda x. t} \text{ ABS}$$

$$\Gamma \vdash s = t$$

$$\Delta \vdash u = v$$

$$types \text{ fit}$$

$$\overline{\Gamma \cup \Delta \vdash s(u) = t(v)} \text{ MK\_COMB}$$

$$\frac{\Gamma \vdash s = t}{\Gamma \vdash t = s} \text{ GSYM}$$

$$\frac{\Gamma \vdash s = t}{\Delta \vdash t = u}$$

$$\frac{\Delta \vdash t = u}{\Gamma \cup \Delta \vdash s = u} \text{ TRANS}$$

$$\frac{\Gamma \vdash p \Leftrightarrow q \qquad \Delta \vdash p}{\Gamma \cup \Delta \vdash q} \text{ EQ\_MP}$$

 $\overline{\vdash (\lambda x. \ t)x = t}$  BETA

### Inference Rules for free Variables

$$\frac{\Gamma[x_1,\ldots,x_n] \vdash p[x_1,\ldots,x_n]}{\Gamma[t_1,\ldots,t_n] \vdash p[t_1,\ldots,t_n]} \text{ INST}$$

$$\frac{\Gamma[\alpha_1,\ldots,\alpha_n] \vdash p[\alpha_1,\ldots,\alpha_n]}{\Gamma[\gamma_1,\ldots,\gamma_n] \vdash p[\gamma_1,\ldots,\gamma_n]} \text{ INST-TYPE}$$

# Inference Rules for Implication

$$\frac{\Delta \vdash p}{\Gamma \cup \Delta \vdash q} \text{ MP, MATCH\_MP} \qquad \frac{\Gamma \vdash p}{\Gamma - \{q\} \vdash q \Longrightarrow p} \text{ DISCH}$$

$$\frac{\Gamma \vdash p = q}{\Gamma \vdash p \Longrightarrow q} \text{ EQ\_IMP\_RULE} \qquad \frac{\Gamma \vdash q \Longrightarrow p}{\Gamma \cup \{q\} \vdash p} \text{ UNDISCH}$$

$$\frac{\Gamma \vdash p \Longrightarrow q}{\Gamma \cup \Delta \vdash p \Longrightarrow p} \text{ IMP\_ANTISYM\_RULE} \qquad \frac{\Gamma \vdash p \Longrightarrow F}{\Gamma \vdash \sim p} \text{ NOT\_INTRO}$$

$$\frac{\Gamma \vdash p \Longrightarrow q}{\Gamma \cup \Delta \vdash p \Longrightarrow r} \text{ IMP\_TRANS}$$

$$\frac{\Delta \vdash q \Longrightarrow r}{\Gamma \cup \Delta \vdash p \Longrightarrow r} \text{ IMP\_TRANS}$$

# Inference Rules for Conjunction / Disjunction

$$\frac{\Gamma \vdash p \qquad \Delta \vdash q}{\Gamma \cup \Delta \vdash p \land q} \text{ CONJ} \qquad \frac{\Gamma \vdash p}{\Gamma \vdash p \lor q} \text{ DISJ1}$$

$$\frac{\Gamma \vdash p \land q}{\Gamma \vdash p} \text{ CONJUNCT1} \qquad \frac{\Gamma \vdash p}{\Gamma \vdash p \lor q} \text{ DISJ2}$$

$$\frac{\Gamma \vdash p \land q}{\Gamma \vdash p \land q} \text{ CONJUNCT2} \qquad \frac{\Gamma \vdash p \lor q}{\Delta_1 \cup \{p\} \vdash r}$$

$$\frac{\Delta_2 \cup \{q\} \vdash r}{\Gamma \cup \Delta_1 \cup \Delta_2 \vdash r} \text{ DISJ\_CASES}$$

### Inference Rules for Quantifiers

$$\frac{\Gamma \vdash p \quad x \text{ not free in } \Gamma}{\Gamma \vdash \forall x. \ p} \text{ GEN} \qquad \frac{\frac{\Gamma \vdash p[u/x]}{\Gamma \vdash \exists x. \ p} \text{ EXISTS}}{\Gamma \vdash \exists x. \ p} \\ \frac{\Gamma \vdash \forall x. \ p}{\Gamma \vdash p[u/x]} \text{ SPEC} \qquad \frac{\Delta \cup \{p[u/x]\} \vdash r}{u \text{ not free in } \Gamma, \Delta, p \text{ and } r} \\ \frac{u \text{ not free in } \Gamma, \Delta, p \text{ and } r}{\Gamma \cup \Delta \vdash r} \text{ CHOOSE}$$

### Forward Proofs

- axioms and inference rules are used to derive theorems
- this method is called forward proof
  - one starts with basic building blocks
  - one moves step by step forward
  - finally the theorem one is interested in is derived
- one can also implement own proof tools

### Forward Proofs — Example I

```
Let's prove \forall p. \ p \Longrightarrow p.
```

```
val IMP_REFL_THM = let
  val tm1 = ''p:bool'';
                              > val tm1 = ''p'': term
  val thm1 = ASSUME tm1:
                              > val thm1 = [p] |- p: thm
 val thm2 = DISCH tm1 thm1;
                             > val thm2 = |- p ==> p: thm
in
  GEN tm1 thm2
                              > val IMP_REFL_THM =
                                   |-!p.p ==> p: thm
end
fun IMP_REFL t =
                              > val IMP_REFL =
  SPEC t IMP_REFL_THM;
                                  fn: term -> thm
```

### Forward Proofs — Example II

Let's prove  $\forall P \ v. \ (\exists x. \ (x = v) \land P \ x) \Longleftrightarrow P \ v.$ 

```
val tm_v = ''v:'a'';
val tm P = ''P:'a -> bool'';
val tm lhs = "?x. (x = v) /\ P x"
val tm_rhs = mk_comb (tm_P, tm_v);
val thm1 = let
                                          > val thm1a = [P v] |- P v: thm
  val thm1a = ASSUME tm_rhs;
                                          > val thm1b =
  val thm1b =
                                               [P v] | - (v = v) / V v : thm
    CONJ (REFL tm_v) thm1a;
                                          > val thm1c =
  val thm1c =
                                               [P v] [-?x. (x = v) / P x]
    EXISTS (tm_lhs, tm_v) thm1b
in
 DISCH tm rhs thm1c
                                          > val thm1 = [] |-
                                               P v \Longrightarrow ?x. (x = v) / P x: thm
end
```

### Forward Proofs — Example II cont.

val thm4 = GENL [tm\_P, tm\_v] thm3

```
val thm2 = let
                                           > val thm2a = \lceil (u = v) / P u \rceil \mid -
  val thm2a =
    ASSUME ((u: a = v) / P u')
                                                (u = v) / P u: thm
                                           > val thm2b = \lceil (u = v) / P u \rceil \mid -
  val thm2b = AP_TERM tm_P
                                               P 11 <=> P v
    (CONJUNCT1 thm2a);
  val thm2c = EQ MP thm2b
                                           > val thm2c = [(u = v) /\ P u] |-
    (CONJUNCT2 thm2a);
                                               Ρv
  val thm2d =
                                           > val thm2d = [?x. (x = v) / Px] | -
    CHOOSE (''u:'a''.
                                               Pν
      ASSUME tm_lhs) thm2c
in
                                           > val thm2 = [] |-
 DISCH tm_lhs thm2d
                                                ?x. (x = y) / P x ==> P y
end
val thm3 = IMP ANTISYM RULE thm2 thm1
                                           > val thm3 = [] |-
```

?x.  $(x = v) / P x \iff P v$ 

?x.  $(x = v) / P x \iff P v$ 

> val thm4 = [] [- !P v.

# Part VII

# **Backward Proofs**

### Motivation I

• let's prove !A B. A /\ B <=> B /\ A

```
(* Show \mid - A / \setminus B ==> B / \setminus A *)
val thm1a = ASSUME ''A /\ B'':
val thm1b = CONJ (CONJUNCT2 thm1a) (CONJUNCT1 thm1a):
val thm1 = DISCH ''A /\ B'' thm1b
(* Show \mid - B \mid A ==> A \mid B *)
val thm2a = ASSUME ''B /\ A'';
val thm2b = CONJ (CONJUNCT2 thm2a) (CONJUNCT1 thm2a):
val thm2 = DISCH ''B /\ A'' thm2b
(* Combine to get |-A| \setminus B \iff B \setminus A *)
val thm3 = IMP_ANTISYM_RULE thm1 thm2
(* Add quantifiers *)
val thm4 = GENL [''A:bool'', ''B:bool''] thm3
```

- this is how you write down a proof
- for finding a proof it is however often useful to think backwards

# Motivation II - thinking backwards

- we want to prove
  - ▶ !A B. A /\ B <=> B /\ A
- all-quantifiers can easily be added later, so let's get rid of them
  - ► A /\ B <=> B /\ A
- now we have an equivalence, let's show 2 implications
  - ► A /\ B ==> B /\ A
  - ▶ B /\ A ==> A /\ B
- we have an implication, so we can use the precondition as an assumption
  - ▶ using A /\ B show B /\ A
  - ▶ A /\ B ==> B /\ A

# Motivation III - thinking backwards

- we have a conjunction as assumption, let's split it
  - ▶ using A and B show B /\ A
  - ► A /\ B ==> B /\ A
- we have to show a conjunction, so let's show both parts
  - using A and B show B
  - using A and B show A
  - ► A /\ B ==> B /\ A
- the first two proof obligations are trivial
  - ► A /\ B ==> B /\ A
- . . .
- we are done

### Motivation IV

- common practise
  - think backwards to find proof
  - write found proof down in forward style
- often switch between backward and forward style within a proof Example: induction proof
  - backward step: induct on . . .
  - forward steps: prove base case and induction case
- whether to use forward or backward proofs depend on
  - support by the interactive theorem prover you use
    - ★ HOL 4 and close family: emphasis on backward proof
    - ★ Isabelle/HOL: emphasis on forward proof
    - ★ Coq : emphasis on backward proof
  - your way of thinking
  - the theorem you try to prove

### **HOL Implementation of Backward Proofs**

- in HOL
  - proof tactics / backward proofs used for most user-level proofs
  - forward proofs used usually for writing automation
- backward proofs are implemented by tactics in HOL
  - decomposition into subgoals implemented in SML
  - ▶ SML datastructures used to keep track of all open subgoals
  - forward proof used to construct theorems
- to understand backward proofs in HOL we need to look at
  - ▶ goal SML datatype for proof obligations
  - ▶ goalStack library for keeping track of goals
  - ▶ tactic SML type for functions performing backward proofs

### Goals

- goals represent proof obligations, i. e. theorems we need/want to prove
- the SML type goal is an abbreviation for term list \* term
- the goal ([asm\_1, ..., asm\_n], c) records that we need/want to prove the theorem  $\{asm_1, ..., asm_n\}$  |- c

### **Example Goals**

#### Goal

([''A'', ''B''], ''A /\ B'') ([''B'', ''A''], ''A /\ B'') ([''B /\ A''], ''A /\ B'')

#### Theorem

 $\{A, B\} \mid -A / \setminus B$  $\{A, B\} \mid -A / \setminus B$ 

 ${B \ / \ A} \ | - A \ / \ B$ 

([], ''(B  $\land$  A) ==> (A  $\land$  B)'') |- (B  $\land$  A) ==> (A  $\land$  B)

#### **Tactics**

- the SML type tactic is an abbreviation for the type goal -> goal list \* validation
- validation is an abbreviation for thm list -> thm
- given a goal, a tactic
  - decides into which subgoals to decompose the goal
  - returns this list of subgoals
  - returns a validation that
    - ★ given a list of theorems for the computed subgoals
    - ★ produces a theorem for the original goal
- special case: empty list of subgoals
  - ▶ the validation (given []) needs to produce a theorem for the goal
- notice: a tactic might be invalid

## Tactic Example — CONJ\_TAC

$$\frac{\Gamma \vdash p \qquad \Delta \vdash q}{\Gamma \cup \Delta \vdash p \ \land \ q} \ \mathrm{CONJ}$$

```
\frac{\texttt{t} \equiv \texttt{conj1} \ / \ \texttt{conj2}}{\frac{\texttt{asl} \vdash \texttt{conj1} \quad \texttt{asl} \vdash \texttt{conj2}}{\texttt{asl} \vdash \texttt{t}}}
```

```
val CONJ_TAC: tactic = fn (asl, t) =>
  let
    val (conj1, conj2) = dest_conj t
  in
    ([(asl, conj1), (asl, conj2)],
      fn [th1, th2] => CONJ th1 th2 | _ => raise Match)
  end
  handle HOL_ERR _ => raise ERR "CONJ_TAC" ""
```

## Tactic Example — EQ\_TAC

```
\frac{\Gamma \vdash p \Longrightarrow q}{\Delta \vdash q \Longrightarrow p} \\
\frac{\Gamma \cup \Delta \vdash p = q}{\Gamma \cup \Delta \vdash p = q}

IMP_ANTISYM_RULE
```

```
t \equiv lhs = rhs
asl \vdash lhs ==> rhs
asl \vdash rhs ==> lhs
asl \vdash t
```

# proofManagerLib / goalStack

- the proofManagerLib keeps track of open goals
- it uses goalStack internally
- important commands
  - ▶ g set up new goal
  - ▶ e expand a tactic
  - ▶ p print the current status
  - ▶ top\_thm get the proved thm at the end

# Tactic Proof Example I

    STRIP_TAC >>
    STRIP_TAC >| [
        ACCEPT_TAC (ASSUME ''B:bool''),
        ACCEPT_TAC (ASSUME ''A:bool'')
    ],
    STRIP_TAC >>
    ASM_REWRITE_TAC[]
]);
```

#### Result

```
val thm =
    |- !A B. A /\ B <=> B /\ A:
    thm
```

## Tactic Proof Example X

## Cleaned-up Tactic

```
val thm = prove (''!A B. A /\ B <=> B /\ A'',
  REPEAT GEN_TAC >>
  EQ_TAC >> (
    REPEAT STRIP_TAC >>
    ASM_REWRITE_TAC []
));
```

### Result

```
val thm =
    |- !A B. A /\ B <=> B /\ A:
    thm
```

# Summary Backward Proofs

- in HOL most user-level proofs are tactic-based
  - ▶ automation often written in forward style
  - low-level, basic proofs written in forward style
  - nearly everything else is written in backward (tactic) style
- there are many different tactics
- in the lecture only the most basic ones will be discussed
- you need to learn about tactics on your own
  - good starting point: Quick manual
  - learning finer points takes a lot of time
  - exercises require you to read up on tactics
- often there are many ways to prove a statement, which tactics to use depends on
  - personal way of thinking
  - personal style and preferences
  - maintainability, clarity, elegance, robustness
  - **>** . . .

# Part VIII

# **Basic Tactics**

## Syntax of Tactics in HOL

- originally tactics were written all in capital letters with underscores
   Example: ALL\_TAC
- since 2010 more and more tactics have overloaded lower-case syntax Example: all\_tac
- sometimes, the lower-case version is shortened Example: REPEAT, rpt
- sometimes, there is special syntax
   Example: THEN, \\, >>
- which one to use is mostly a matter of personal taste
  - all-capital names are hard to read and type
  - however, not for all tactics there are lower-case versions
  - mixed lower- and upper-case tactics are even harder to read
  - often shortened lower-case name is not speaking

In the lecture we will use mostly the old-style names.

#### Some Basic Tactics

GEN_TAC	remove outermos	t all-quantifier
---------	-----------------	------------------

DISCH\_TAC move antecedent of goal into assumptions

CONJ\_TAC splits conjunctive goal

STRIP\_TAC splits on outermost connective (combination

of GEN\_TAC, CONJ\_TAC, DISCH\_TAC, ...)

DISJ1\_TAC selects left disjunct selects right disjunct

EQ\_TAC reduce Boolean equality to implications

ASSUME\_TAC thm add theorem to list of assumptions

EXISTS TAC term provide witness for existential goal

EXISTS\_TAC term provide witness for existential goal

#### **Tacticals**

- tacticals are SML functions that combine tactics to form new tactics
- common workflow
  - develop large tactic interactively
  - using goalStack and editor support to execute tactics one by one
  - combine tactics manually with tacticals to create larger tactics
  - finally end up with one large tactic that solves your goal
  - use prove or store\_thm instead of goalStack
- make sure to clearly mark proof structure by e.g.
  - use indentation
  - use parentheses
  - use appropriate connectives
  - **.** . . .
- goalStack commands like e or g should not appear in your final proof

## Some Basic Tacticals

tac1 >> tac2	THEN, \\	applies tactics in sequence
tac >  tacL	THENL	applies list of tactics to subgoals
tac1 >- tac2	THEN1	applies tac2 to the first subgoal of tac1
REPEAT tac	rpt	repeats tac until it fails
NTAC n tac		apply tac n times
REVERSE tac	reverse	reverses the order of subgoals
tac1 ORELSE tac2		applies tac1 only if tac2 fails
TRY tac		do nothing if tac fails
ALL_TAC	$all\_tac$	do nothing
$NO_{-}TAC$		fail

#### Basic Rewrite Tactics

- (equational) rewriting is at the core of HOL's automation
- we will discuss it in detail later
- details complex, but basic usage is straightforward
  - ▶ given a theorem rewr\_thm of form |- P x = Q x and a term t
  - rewriting t with rewr\_thm means
  - ▶ replacing each occurrence of a term P c for some c with Q c in t
- warning: rewriting may loop
   Example: rewriting with theorem |- X <=> (X /\ T)

REWRITE\_TAC thms

ASM\_REWRITE\_TAC thms
ONCE\_REWRITE\_TAC thms
ONCE\_ASM\_REWRITE\_TAC thms

rewrite goal using equations found in given list of theorems in addition use assumptions rewrite once in goal using equations rewrite once using assumptions

## Case-Split and Induction Tactics

Induct on 'term'

Induct

Cases\_on 'term'

Cases

MATCH MP TAC thm

IRULE\_TAC thm

case-split on all-quantor

apply rule

induct on term

generalised apply rule

induct on all-quantor

case-split on term

## **Assumption Tactics**

POP\_ASSUM thm-tac

PAT\_ASSUM term thm-tac also PAT\_X\_ASSUM term thm-tac

WEAKEN\_TAC term-pred

use and remove first assumption common usage POP\_ASSUM MP\_TAC

use (and remove) first assumption matching pattern

removes first assumption satisfying predicate

#### Decision Procedure Tactics

- decision procedures try to solve the current goal completely
- they either succeed of fail
- no partial progress
- decision procedures vital for automation

TAUT\_TAC propositional logic tautology checker

DECIDE\_TAC linear arithmetic for num

METIS\_TAC thms first order prover

numLib.ARITH\_TAC Presburger arithmetic

intLib.ARITH\_TAC uses Omega test

# **Subgoal Tactics**

- it is vital to structure your proofs well
  - improved maintainability
  - improved readability
  - improved reusability
  - ▶ saves time in medium-run
- therefore, use many small lemmata
- also, use many explicit subgoals

'term-frag' by tac show term with tac and add it to assumptions

'term-frag' sufficies\_by tac show it sufficies to prove term

# Term Fragments / Term Quotations

- notice that by and sufficies\_by take term fragments
- term fragments are also called **term quotations**
- they represent (partially) unparsed terms
- parsing takes time place during execution of tactic in context of goal
- this helps to avoid type annotations
- however, this means syntax errors show late as well
- the library Q defines many tactics using term fragments

## Importance of Exercises

- here many tactics are presented in a very short amount of time
- there are many, many more important tactics out there
- few people can learn a programming language just by reading manuals
- similar few people can learn HOL just by reading and listening
- you should write your own proofs and play around with these tactics
- solving the exercises is highly recommended (and actually required if you want credits for this course)

- we want to prove !1. LENGTH (APPEND 1 1) = 2 \* LENGTH 1
- first step: set up goal on goalStack
- at same time start writing proof script

## Proof Script

```
val LENGTH_APPEND_SAME = prove (
    ''!1. LENGTH (APPEND 1 1) = 2 * LENGTH 1'',
```

- run g ''!1. LENGTH (APPEND 1 1) = 2 \* LENGTH 1''
- this is done by hol-mode
- move cursor inside term and press M-h g
   (menu-entry HOL Goalstack New goal)

#### Current Goal

```
!1. LENGTH (1 ++ 1) = 2 * LENGTH 1
```

- the outermost connective is an all-quantor
- let's get rid of it via GEN\_TAC

## **Proof Script**

```
val LENGTH_APPEND_SAME = prove (
    ''!1. LENGTH (1 ++ 1) = 2 * LENGTH 1'',
GEN_TAC
```

- run e GEN\_TAC
- this is done by hol-mode
- mark line with GEN\_TAC and press M-h e (menu-entry HOL - Goalstack - Apply tactic)

#### Current Goal

```
LENGTH (1 ++ 1) = 2 * LENGTH 1
```

- LENGTH of APPEND can be simplified
- let's search an appropriate lemma with DB.match

- run DB.print\_match [] ''LENGTH (\_ ++ \_)''
- this is done via hol-mode
- press M-h m and enter term pattern (menu-entry HOL - Misc - DB match)
- this finds the theorem listTheory.LENGTH\_APPEND
  - |- !11 12. LENGTH (11 ++ 12) = LENGTH 11 + LENGTH 12

### Current Goal

```
LENGTH (1 ++ 1) = 2 * LENGTH 1
```

• let's rewrite with found theorem listTheory.LENGTH\_APPEND

## **Proof Script**

```
val LENGTH_APPEND_SAME = prove (
    ''!1. LENGTH (APPEND 1 1) = 2 * LENGTH 1'',
GEN_TAC >>
REWRITE_TAC[listTheory.LENGTH_APPEND]
```

- connect the new tactic with tactical >> (THEN)
- use hol-mode to expand the new tactic

#### Current Goal

```
LENGTH 1 + LENGTH 1 = 2 * LENGTH 1
```

- let's search a theorem for simplifying 2 \* LENGTH 1
- prepare for extending the previous rewrite tactic

## **Proof Script**

```
val LENGTH_APPEND_SAME = prove (
    ''!1. LENGTH (APPEND 1 1) = 2 * LENGTH 1'',
GEN_TAC >>
REWRITE_TAC[listTheory.LENGTH_APPEND]
```

- DB.match finds theorem arithmeticTheory.TIMES2
- press M-h b and undo last tactic expansion (menu-entry HOL - Goalstack - Back up)

#### Current Goal

```
LENGTH (1 ++ 1) = 2 * LENGTH 1
```

- extend the previous rewrite tactic
- finish proof

## Proof Script

```
val LENGTH_APPEND_SAME = prove (
    ''!1. LENGTH (APPEND 1 1) = 2 * LENGTH 1'',
GEN_TAC >>
REWRITE_TAC[listTheory.LENGTH_APPEND, arithmeticTheory.TIMES2]);
```

- add TIMES2 to the list of theorems used by rewrite tactic
- use hol-mode to expand the extended rewrite tactic
- goal is solved, so let's add closing parenthesis and semicolon

- we have a finished tactic proving our goal
- notice that GEN\_TAC is not needed
- let's polish the proof script

```
Proof Script
val LENGTH_APPEND_SAME = prove (
    ''!1. LENGTH (APPEND 1 1) = 2 * LENGTH 1'',
GEN_TAC >>
REWRITE_TAC[listTheory.LENGTH_APPEND, arithmeticTheory.TIMES2]);
```

```
Polished Proof Script
val LENGTH_APPEND_SAME = prove (
   ''!1. LENGTH (APPEND 1 1) = 2 * LENGTH 1'',
REWRITE_TAC[listTheory.LENGTH_APPEND, arithmeticTheory.TIMES2]);
```

- let's prove something slightly more complicated
- drop old goal by pressing M-h d (menu-entry HOL - Goalstack - Drop goal)
- set up goal on goalStack (M-h g)
- at same time start writing proof script

## **Proof Script**

#### Current Goal

```
!x1 x2 x3 11 12 13.

(MEM x1 11 /\ MEM x2 12 /\ MEM x3 13) /\
x1 <= x2 /\ x2 <= x3 /\ x3 <= SUC x1 ==>
~ALL_DISTINCT (11 ++ 12 ++ 13)
```

let's strip the goal

## **Proof Script**

#### Current Goal

```
!x1 x2 x3 l1 l2 l3.

(MEM x1 l1 /\ MEM x2 l2 /\ MEM x3 l3) /\
x1 <= x2 /\ x2 <= x3 /\ x3 <= SUC x1 ==>
~ALL_DISTINCT (l1 ++ l2 ++ l3)
```

let's strip the goal

## **Proof Script**

```
val LENGTH_APPEND_SAME = prove (
    ''!1. LENGTH (APPEND 1 1) = 2 * LENGTH 1'',
REPEAT STRIP_TAC
```

#### **Actions**

- add REPEAT STRIP\_TAC to proof script
- expand this tactic using hol-mode

#### Current Goal

#### F

-----

- 0. MEM x1 11 4.  $x2 \le x3$
- 1. MEM x2 12 5. x3 <= SUC x1
- 2. MEM x3 13 6. ALL\_DISTINCT (11 ++ 12 ++ 13)
- 3.  $x1 \le x2$
- oops, we did too much, we would like to keep ALL\_DISTINCT in goal

## **Proof Script**

```
val NOT_ALL_DISTINCT_LEMMA = prove (''...',
REPEAT GEN_TAC >> STRIP_TAC
```

#### **Actions**

- undo REPEAT STRIP\_TAC (M-h b)
- expand more fine-tuned strip tactic

## Current Goal

```
~ALL_DISTINCT (11 ++ 12 ++ 13)
```

- 0. MEM x1 11 3.  $x1 \le x2$
- 1. MEM x2 12 4. x2 <= x3
- 2. MEM x3 13 5. x3 <= SUC x1
- now let's simplify ALL\_DISTINCT
- search suitable theorems with DB.match
- use them with rewrite tactic

## **Proof Script**

```
val NOT_ALL_DISTINCT_LEMMA = prove (''...'',
REPEAT GEN TAC >> STRIP TAC >>
REWRITE_TAC[listTheory.ALL_DISTINCT_APPEND, listTheory.MEM_APPEND]
```

#### Current Goal

~((ALL\_DISTINCT 11 /\ ALL\_DISTINCT 12 /\ !e. MEM e 11 ==> ~MEM e 12) /\ ALL\_DISTINCT 13 /\ !e. MEM e 11 \/ MEM e 12 ==> ~MEM e 13)

```
-----
```

- 0. MEM x1 11 3.  $x1 \le x2$
- 1. MEM x2 12 4. x2 <= x3
- 2. MEM x3 13 5. x3 <= SUC x1
- from assumptions 3, 4 and 5 we know  $x2 = x1 \ / \ x2 = x3$
- let's deduce this fact by DECIDE\_TAC

### **Proof Script**

```
val NOT_ALL_DISTINCT_LEMMA = prove (''...',
REPEAT GEN_TAC >> STRIP_TAC >>
REWRITE_TAC[listTheory.ALL_DISTINCT_APPEND, listTheory.MEM_APPEND] >>
'(x2 = x1) \/ (x2 = x3)' by DECIDE_TAC
```

## Current Goals — 2 subgoals, one for each disjunct

- both goals are easily solved by first-order reasoning
- let's use METIS\_TAC[] for both subgoals

## Finished Proof Script

- notice that proof structure is explicit
- parentheses and indentation used to mark new subgoals

# Part IX

# Induction Proofs

## Mathematical Induction

- mathematical (a. k. a. natural) induction principle: If a property P holds for 0 and P(n) implies P(n+1) for all n, then P(n) holds for all n.
- HOL is expressive enough to encode this principle as a theorem.

```
|-!P.P0/\ (!n.Pn ==> P (SUC n)) ==> !n.Pn
```

- Performing mathematical induction in HOL means applying this theorem (e. g. via HO\_MATCH\_MP\_TAC)
- there are many similarish induction theorems in HOL
- Example: complete induction principle

```
|-!P. (!n. (!m. m < n ==> P m) ==> P n) ==> !n. P n
```

#### Structural Induction Theorems

- structural induction theorems are an important special form of induction theorems
- they describe performing induction on the structure of a datatype
- Example: |- !P. P [] /\ (!t. P t ==> !h. P (h::t)) ==> !1. P 1
- structural induction is used very frequently in HOL
- for each algabraic datatype, there is an induction theorem

#### Other Induction Theorems

- there are many induction theorems in HOL
  - datatype definitions lead to induction theorems
  - recursive function definitions produce corresponding induction theorems
  - recursive relation definitions give rise to induction theorems
  - many are manually defined

#### Examples

# Induction (and Case-Split) Tactics

- the tactic Induct (or Induct\_on) usually used to start induction proofs
- it looks at the type of the quantifier (or its argument) and applies the default induction theorem for this type
- this is usually what one needs
- other (non default) induction theorems can be applied via INDUCT\_THEN or HO\_MATCH\_MP\_TAC
- similarish Cases\_on picks and applies default case-split theorems

## Induction Proof - Example I - Slide 1

- let's prove via induction
  - !11 12. REVERSE (11 ++ 12) = REVERSE 12 ++ REVERSE 11
- we set up the goal and start and induction proof on 11

## **Proof Script**

```
val REVERSE_APPEND = prove (
''!11 12. REVERSE (11 ++ 12) = REVERSE 12 ++ REVERSE 11'',
Induct
```

## Induction Proof - Example I - Slide 2

- the induction tactic produced two cases
- base case:

```
!12. REVERSE ([] ++ 12) = REVERSE 12 ++ REVERSE []
```

induction step:

both goals can be easily proved by rewriting

```
Proof Script
```

```
val REVERSE_APPEND = prove (''
!11 12. REVERSE (11 ++ 12) = REVERSE 12 ++ REVERSE 11'',
Induct >| [
   REWRITE_TAC[REVERSE_DEF, APPEND, APPEND_NIL],
   ASM_REWRITE_TAC[REVERSE_DEF, APPEND, APPEND_ASSOC]
]);
```

## Induction Proof - Example II - Slide 2

- let's prove via induction
  - !1. REVERSE  $(REVERSE \ 1) = 1$
- we set up the goal and start and induction proof on 1

## **Proof Script**

```
val REVERSE_REVERSE = prove (
''!1. REVERSE (REVERSE 1) = 1'',
Induct
```

## Induction Proof - Example II - Slide 2

- the induction tactic produced two cases
- base case:

```
REVERSE (REVERSE []) = []
```

• induction step:

again both goals can be easily proved by rewriting

## **Proof Script**

```
val REVERSE_REVERSE = prove (
''!1. REVERSE (REVERSE 1) = 1'',
Induct >| [
   REWRITE_TAC[REVERSE_DEF],
   ASM_REWRITE_TAC[REVERSE_DEF, REVERSE_APPEND, APPEND]
]);
```

# Part X

# **Basic Definitions**

#### **Definitional Extensions**

- there are conservative definition principles for types and constants
- conservative means that all theorems that can be proved in extended theory can also be proved in original one
- however, such extensions make the theory more comfortable
- definitions introduce no new inconsistencies
- the HOL community has a very strong tradition of a purely definitional approach

#### Axiomatic Extensions

- axioms are a different approach
- they allow postulating arbitrary properties, i. e. extending the logic with arbitrary theorems
- this approach might introduce new inconsistencies
- in HOL axioms are very rarely needed
- using definitions is often considered more elegant
- it is hard to keep track of axioms
- use axioms only if you really know what you are doing

### **Oracles**

- oracles are families of axioms
- however, they are used differently than axioms
- they are used to enable usage of external tools and knowledge
- you might want to use an external automated prover
- this external tool acts as an oracle
  - it provides answers
  - it does not explain or justify these answers
- you don't know, whether this external tool might be buggy
- all theorems proved via it are tagged with a special oracle-tag
- tags are propagated
- this allows keeping track of everything depending on the correctness of this tool

#### Oracles II

- Common oracle-tags
  - ▶ DISK\_THM theorem was written to disk and read again
  - ► HolSatLib proved by MiniSat
  - HolSmtLib proved by external SMT solver
  - fast\_proof proof was skipped to compile a theory rapidly
  - ▶ cheat we cheated :-)
- cheating via e.g. the cheat tactic means skipping proofs
- it can be helpful during proof development
  - test whether some lemmata allow you finishing the proof
  - skip lengthy but boring cases and focus on critical parts first
  - experiment with exact form of invariants
- cheats should be removed reasonable quickly
- HOL warns about cheats and skipped proofs

# Pitfalls of Definitional Approach

- definitions can't introduce new inconsistencies
- they force you to state all assumed properties at one location
- however, you still need to be careful
- Is your definition really expressing what you had in mind?
- Does your formalisation correspond to the real world artefact ?
- How can you convince others that this is the case ?
- we will discuss methods to deal with this later in this course
  - formal sanity
  - conformance testing
  - code review
  - comments, good names, clear coding style
- this is highly complex and needs a lot of effort in general

## **Specifications**

 HOL allows to introduce new constants with certain properties, provided the existence of such constants has been shown

- new\_specification is a convenience wrapper
  - ▶ it uses existential quantification instead of Hilbert's choice
  - deals with pair syntax
  - stores resulting definitions in theory
- new\_specification captures the underlying principle nicely

### **Definitions**

val double\_def =

special case: new constant defined by equality

```
Specification with Equality
> double_EXISTS
val it =
|- ?double. (!n. double n = (n + n))
> val double_def = new_specification ("double_def", ["double"], double_EXISTS);
```

• there is a specialised methods for such non-recursive definitions

#### Non Recursive Definitions

l-!n. double n = n + n

#### Restrictions for Definitions

- all variables occurring on right-hand-side (rhs) need to be arguments
  - ▶ e.g. new\_definition (..., ''F n = n + m'') fails
  - ▶ m is free on rhs
- all type variables occurring on rhs need to occur on lhs

  - IS\_FIN\_TY would lead to inconsistency
  - ▶ |- FINITE (UNIV : bool set)
  - ► |- ~FINITE (UNIV : num set)
  - ► T <=> FINITE (UNIV:bool set) <=> IS\_FIN\_TY <=>
    - FINITE (UNIV:num set) <=> F
  - therefore, such definitions can't be allowed

## **Underspecified Functions**

- function specification do not need to define the function precisely
- multiple different functions satisfying one spec are possible
- functions resulting from such specs are called underspecified
- underspecified functions are still total, one just lacks knowledge
- one common application: modelling partial functions
  - ▶ functions like e.g. HD and TL are total
  - they are defined for empty lists
  - however, it is not specified, which value they have for empty lists
  - only known: HD [] = HD [] and TL [] = TL []
    val MY\_HD\_EXISTS = prove (''?hd. !x xs. (hd (x::xs) = x)'', ...);
    val MY\_HD\_SPEC =
     new\_specification ("MY\_HD\_SPEC", ["MY\_HD"], MY\_HD\_EXISTS)

# Primitive Type Definitions

- HOL allows introducing non-empty subtypes of existing types
- a predicate P : ty -> bool describes a subset of an existing type ty
- ty may contain type variables
- only non-empty types are allowed
- therefore a non-emptyness proof ex-thm of form ?e. P e is needed
- new\_type\_definition (op-name, ex-thm) then introduces a new type op-name specified by P

## Primitive Type Definitions - Example 1

- lets try to define a type dlist of lists containing no duplicates
- predicate ALL\_DISTINCT : 'a list -> bool is used to define it
- easy to prove theorem dlist\_exists: |- ?1. ALL\_DISTINCT 1
- val dlist\_TY\_DEF = new\_type\_definitions("dlist", dlist\_exists) defines a new type 'a dlist and returns a theorem

```
|- ?(rep :'a dlist -> 'a list).
     TYPE_DEFINITION ALL_DISTINCT rep
```

- rep is a function taking a 'a dlist to the list representing it
  - ► rep is injective
  - ▶ a list satisfies ALL\_DISTINCT iff there is a corresponding dlist

## Primitive Type Definitions - Example 2

 define\_new\_type\_bijections can be used to define bijections between old and new type

- other useful theorems can be automatically proved by
  - prove\_abs\_fn\_one\_one
  - prove\_abs\_fn\_onto
  - prove\_rep\_fn\_one\_one
  - prove\_rep\_fn\_onto

# Primitive Definition Principles Summary

- primitive definition principles are easily explained
- they lead to conservative extensions
- however, they are cumbersome to use
- LCF approach allows implementing more convenient definition tools
  - ► Datatype package
  - TFL (Total Functional Language) package
  - ► IndDef (Inductive Definition) package
  - quotientLib Quotient Types Library
  - **.**..

# **Functional Programming**

- the Datatype package allows to define datatypes conveniently
- the TFL package allows to define (mutually recursive) functions
- the EVAL conversion allows evaluating those definitions
- this gives many HOL developments the feeling of a functional program
- there is really a close connection between functional programming a definitions in HOL
  - functional programming design principles apply
  - ► EVAL is a great way to test quickly, whether your definitions are working as intended

## Functional Programming Example

## Datatype Package

- the Datatype package allows to define SML style datatypes easily
- there is support for
  - algebraic datatypes
  - record types
  - mutually recursive types
  - **...**
- many constants are automatically introduced
  - constructors
  - case-split constant
  - size function
  - field-update and accessor functions for records
  - **.**...
- many theorems are derived and stored in current theory
  - injectivity and distinctness of constructors
  - nchotomy and structural induction theorems
  - rewrites for case-split, size and record update functions
  - **.**..

# Datatype Package - Example I

## Tree Datatype in SML

```
datatype ('a,'b) btree = Leaf of 'a
| Node of ('a,'b) btree * 'b * ('a,'b) btree
```

## Tree Datatype in HOL

```
Datatype 'btree = Leaf 'a | Node btree 'b btree'
```

## Tree Datatype in HOL — Deprecated Syntax

# Datatype Package - Example I - Derived Theorems 1

#### btree\_distinct

|- !a2 a1 a0 a. Leaf a <> Node a0 a1 a2

#### btree\_11

```
|- (!a a'. (Leaf a = Leaf a') <=> (a = a')) /\
    (!a0 a1 a2 a0' a1' a2'.
        (Node a0 a1 a2 = Node a0' a1' a2') <=>
        (a0 = a0') /\ (a1 = a1') /\ (a2 = a2'))
```

#### btree\_nchotomy

```
|-!bb. (?a. bb = Leaf a) \/ (?b b1 b0. bb = Node b b1 b0)
```

#### btree\_induction

# Datatype Package - Example I - Derived Theorems 2

#### btree\_size\_def

```
|- (!f f1 a. btree_size f f1 (Leaf a) = 1 + f a) /\
  (!f f1 a0 a1 a2.
   btree_size f f1 (Node a0 a1 a2) =
   1 + (btree_size f f1 a0 + (f1 a1 + btree_size f f1 a2)))
```

#### bbtree\_case\_def

```
|- (!a f f1. btree_CASE (Leaf a) f f1 = f a) /\
   (!a0 a1 a2 f f1. btree_CASE (Node a0 a1 a2) f f1 = f1 a0 a1 a2)
```

### btree\_case\_cong

```
|- !M M' f f1.
   (M = M') /\ (!a. (M' = Leaf a) ==> (f a = f' a)) /\
   (!a0 a1 a2.
        (M' = Node a0 a1 a2) ==> (f1 a0 a1 a2 = f1' a0 a1 a2)) ==>
   (btree_CASE M f f1 = btree_CASE M' f' f1')
```

# Datatype Package - Example II

## Enumeration type in SML

datatype my\_enum = E1 | E2 | E3

### Enumeration type in HOL

Datatype 'my\_enum = E1 | E2 | E3'

## Datatype Package - Example II - Derived Theorems

#### my\_enum\_nchotomy

|- !P. P E1 /\ P E2 /\ P E3 ==> !a. P a

#### my\_enum\_distinct

|- E1 <> E2 /\ E1 <> E3 /\ E2 <> E3

#### my\_enum2num\_thm

|-  $(my_enum2num E1 = 0) / (my_enum2num E2 = 1) / (my_enum2num E3 = 2)$ 

#### my\_enum2num\_num2my\_enum

 $|-!r.r < 3 \iff (my_enum2num (num2my_enum r) = r)$ 

## Datatype Package - Example III

### Record type in SML

```
type rgb = \{ r : int, g : int, b : int \}
```

### Record type in HOL

```
Datatype 'rgb = < | r : num; g : num; b : num |>'
```

## Datatype Package - Example III - Derived Theorems

#### rgb\_component\_equality

#### rgb\_nchotomy

|- !rr. ?n n0 n1. rr = rgb n n0 n1

#### rgb\_r\_fupd

|- !f n n0 n1. rgb n n0 n1 with r updated\_by f = rgb (f n) n0 n1

#### rgb\_updates\_eq\_literal

```
|- !r n1 n0 n.
r with <|r := n1; g := n0; b := n|> = <|r := n1; g := n0; b := n|>
```

## Datatype Package - Example IV

- nested record types are not allowed
- however, mutual recursive types can mitigate this restriction

## Filesystem Datatype in SML

### **Not Supported** Nested Record Type Example in HOL

### Filesystem Datatype - Mutual Recursion in HOL

# Datatype Package - No support for Co-Algebraic Types

KTH VETENSES SCH KONST

- there is no support for co-algebraic types
- the Datatype package could be extended to do so
- other systems like Isabelle/HOL provide high-level methods for defining such types

```
Co-algebraic Type Example in SML — Lazy Lists
```

## Datatype Package - Discussion

- Datatype package allows to define many useful datatypes
- however, there are many limitations
  - some types cannot be defined in HOL, e.g. empty types
  - some types are not supported, e.g. co-algebraic types
  - there are bugs (currently e.g. some trouble with certain mutually recursive definitions)
- biggest restrictions in practice (in my opinion and my line of work)
  - no support for co-algebraic datatypes
  - no nested record datatypes
- depending on datatype, different sets of useful lemmata are derived
- most important ones are added to TypeBase
  - tools like Induct\_on, Cases\_on use them
  - there is support for pattern matching

## Total Functional Language (TFL) package

- TFL package implements support for terminating functional definitions
- Define defines functions from high-level descriptions
- there is support for pattern matching
- look and feel is like function definitions in SML
- based on well-founded recursion principle
- Define is the most common way for definitions in HOL

#### Well-Founded Relations

• a relation R : 'a -> 'a -> bool is called **well-founded**, iff there are no infinite descending chains

```
wellfounded R = \sim ?f. !n. R (f (SUC n)) (f n)
```

- Example: \$< : num -> num -> bool is well-founded
- if arguments of recursive calls are smaller according to well-founded relation, the recursion terminates
- this is the essence of termination proofs

#### Well-Founded Recursion

- a well-founded relation R can be used to define recursive functions
- this recursion principle is called WFREC in HOL
- idea of WFREC
  - ▶ if arguments get smaller according to R, perform recursive call
  - otherwise abort and return ARB
- WFREC always defines a function
- if all recursive calls indeed decrease according to R, the original recursive equations can be derived from the WFREC representation
- TFL uses this internally
- however, this is well-hidden from the user

### Define - Initial Examples

### Simple Definitions

```
> val DOUBLE_def = Define 'DOUBLE n = n + n'
val DOUBLE_def =
   |-!n. DOUBLE n = n + n:
  thm
> val MY LENGTH def = Define '(MY LENGTH [] = 0) /\
                              (MY_LENGTH (x::xs) = SUC (MY_LENGTH xs))'
val MY LENGTH def =
   |- (MY_LENGTH [] = 0) /\ !x xs. MY_LENGTH (x::xs) = SUC (MY_LENGTH xs):
  thm
> val MY_APPEND_def = Define '(MY_APPEND [] vs = vs) /\
                              (MY\_APPEND (x::xs) ys = x :: (MY\_APPEND xs ys))
val MY APPEND def =
   [-(!ys. MY\_APPEND [] ys = ys) /
      (!x xs ys. MY_APPEND (x::xs) ys = x::MY_APPEND xs ys):
  thm
```

#### Define discussion

- Define feels like a function definition in HOL
- it can be used to define "terminating" recursive functions
- Define is implemented by a large, non-trivial piece of SML code
- it uses many heuristics
- outcome of <u>Define</u> sometimes hard to predict
- the input descriptions are only hints
  - the produced function and the definitional theorem might be different
  - in simple examples, quantifiers added
  - pattern compilation takes place
  - earlier "conjuncts" have precedence

### Define - More Examples

```
> val MY HD def = Define 'MY HD (x :: xs) = x'
val MY_HD_def = |-!x xs. MY_HD (x::xs) = x : thm
> val IS SORTED def = Define '
     (IS\_SORTED (x1 :: x2 :: xs) = ((x1 < x2) / (IS\_SORTED (x2 :: xs)))) /
    (IS SORTED = T)'
val IS_SORTED_def =
   |- (!xs x2 x1. IS_SORTED (x1::x2::xs) <=> x1 < x2 /\ IS_SORTED (x2::xs)) /\
      (IS SORTED [] <=> T) /\ (!v. IS SORTED [v] <=> T)
> val EVEN def = Define '(EVEN 0 = T) /\ (ODD 0 = F) /\
                         (EVEN (SUC n) = ODD n) / \setminus (ODD (SUC n) = EVEN n)
val EVEN_def =
   |- (EVEN 0 <=> T) /\ (ODD 0 <=> F) /\ (!n. EVEN (SUC n) <=> ODD n) /\
      (!n. ODD (SUC n) \iff EVEN n) : thm
> val ZIP_def = Define '(ZIP (x::xs) (y::ys) = (x,y)::(ZIP xs ys)) /
                        (ZIP = [])'
val ZIP def =
   |-(!ys y xs x. ZIP (x::xs) (y::ys) = (x,y)::ZIP xs ys) /
      (!v1. ZIP [] v1 = []) / (!v4 v3. ZIP (v3::v4) [] = []) : thm
```

### **Primitive Definitions**

- Define introduces (if needed) the function using WFREC
- intended definition derived as a theorem
- the theorems are stored in current theory
- usually, one never needs to look at it

### Examples

```
val IS_SORTED_primitive_def =
|- IS_SORTED =
    WFREC (@R. WF R /\ !x1 xs x2. R (x2::xs) (x1::x2::xs))
    (\IS_SORTED a.
        case a of
        [] => I T
        | [x1] => I T
        | x1::x2::xs => I (x1 < x2 /\ IS_SORTED (x2::xs)))

|- !R M. WF R ==> !x. WFREC R M x = M (RESTRICT (WFREC R M) R x) x
|- !f R x. RESTRICT f R x = (\y. if R y x then f y else ARB)
```

#### Induction Theorems

- Define automatically defines induction theorems
- these theorems are stored in current theory with suffix ind
- use DB.fetch "-" "something\_ind" to retrieve them
- these induction theorems are useful to reason about corresponding recursive functions

### Example

```
val IS_SORTED_ind = |- !P.
    ((!x1 x2 xs. P (x2::xs) ==> P (x1::x2::xs)) /\
    P [] /\
    (!v. P [v])) ==>
!v. P v
```

## Define failing

- Define might fail for various reasons to define a function
  - such a function cannot be defined in HOL
  - such a function can be defined, but not via the methods used by TFL
  - ► TFL can define such a function, but its heuristics are too weak and user guidance is required
  - there is a bug :-)
- termination is an important concept for Define
- it is easy to misunderstand termination in the context of HOL
- we need to understand what is meant by termination

#### Termination in HOL

- in SML it is natural to talk about termination of functions
- in the HOL logic there is no concept of execution
- thus, there is no concept of termination in HOL

#### 3 characterisations of a function f : num -> num

```
|-!n. f n = 0
```

$$\rightarrow$$
 |- (f 0 = 0) /\ !n. (f (SUC n) = f n)

$$\mid$$
 - (f 0 = 0) /\ !n. (f n = f (SUC n))

Is f terminating? All 3 theorems are equivalent.

#### Termination in HOL II

- it is useful to think in terms of termination
- the TFL package implements heuristics to define functions that would terminate in SML
- the TFL package uses well-founded recursion
- the required well-founded relation corresponds to a termination proof
- therefore, it is very natural to think of Define searching a termination proof
- important: this is the idea behind this function definition package, not a property of HOL

HOL is not limited to "terminating" functions

#### Termination in HOL III

- one can define "non-terminating" functions in HOL
- however, one cannot do so (easily) with Define

#### Definition of WHILE in HOL

```
|- !P g x. WHILE P g x = if P x then WHILE P g (g x) else x
```

#### **Execution Order**

There is no "execution order". One can easily define a complicated constant function:

```
(myk : num \rightarrow num) (n:num) = (let x = myk (n+1) in 0)
```

#### **Unsound Definitions**

A function  ${\tt f}: {\tt num} \to {\tt num}$  with the following property cannot be defined in HOL unless HOL has an inconsistancy:

```
!n. f n = ((f n) + 1)
```

Such a function would allow to prove 0 = 1.

#### Manual Termination Proofs I

- TFL uses various heuristics to find a well-founded relation
- however, these heuristics may not be strong enough
- in such cases the user can provide a well-founded relation manually
- the most common well-founded relations are measures
- measures map values to natural numbers and use the less relation
   |-!(f:'a -> num) x y. measure f x y <=> (f x < f y)</li>
- all measures are well-founded: |- !f. WF (measure f)
- moreover, existing well-founded relations can be combined
  - lexicographic order LEX
  - list lexicographic order LLEX
  - **.** . . .

#### Manual Termination Proofs II

- if Define fails to find a termination proof, Hol\_defn can be used
- Hol\_defn defers termination proofs
- it derives termination conditions and sets up the function definitions
- all results are packaged as a value of type defn
- after calling Hol\_defn the defined function(s) can be used
- however, the intended definition theorem has not been derived yet
- to derive it, one needs to
  - provide a well-founded relation
  - show that termination conditions respect that relation
- Defn.tprove and Defn.tgoal are intended for this
- proofs usually start by providing relation via tactic WF\_REL\_TAC

```
> val qsort_defn = Hol_defn "qsort" '
  (gsort ord [] = []) /\
  (qsort ord (x::rst) =
     (gsort ord (FILTER ($~ o ord x) rst)) ++
     [x] ++
     (qsort ord (FILTER (ord x) rst)))'
val qsort_defn = HOL function definition (recursive)
Equation(s):
 [...] |- qsort ord [] = []
 [...] |- qsort ord (x::rst) =
            qsort ord (FILTER ($~ o ord x) rst) ++ [x] ++
            qsort ord (FILTER (ord x) rst)
Induction: ...
Termination conditions :
 0. !rst x ord. R (ord.FILTER (ord x) rst) (ord.x::rst)
 1. !rst x ord. R (ord, FILTER ($~ o ord x) rst) (ord, x::rst)
 2. WF R
```

```
> Defn.tgoal qsort_defn
Initial goal:
?R.,
 WF R. /\
 (!rst x ord. R (ord,FILTER (ord x) rst) (ord,x::rst)) /\
 (!rst x ord. R (ord,FILTER ($~ o ord x) rst) (ord,x::rst))
> e (WF_REL_TAC 'measure (\((_, 1). LENGTH 1)')
1 subgoal :
(!rst x ord. LENGTH (FILTER (ord x) rst) < LENGTH (x::rst)) /\
(!rst x ord. LENGTH (FILTER (\x'. ~ord x x') rst) < LENGTH (x::rst))
> ...
```

```
> val (qsort_def, qsort_ind) =
 Defn.tprove (qsort_defn,
   WF_REL_TAC 'measure (\((_, 1). LENGTH 1)') >> ...)
val gsort_def =
|- (qsort ord [] = []) /\
   (qsort ord (x::rst) =
   qsort ord (FILTER ($~ o ord x) rst) ++ [x] ++
   qsort ord (FILTER (ord x) rst))
val gsort_ind =
|- !P. (!ord. P ord []) /\
       (!ord x rst.
         P ord (FILTER (ord x) rst) /\
         P ord (FILTER ($~ o ord x) rst) ==>
         P ord (x::rst)) ==>
       Iv v1. P v v1
```

## Part XI

# **Good Definitions**

### Importance of Good Definitions

- using good definitions is very important
  - good definitions are vital for clarity
  - proofs depend a lot on the form of definitions
- unluckily, it is hard to state what a good definition is
- even harder to come up with good definitions
- let's look at it a bit closer anyhow

## Importance of Good Definitions — Clarity I

- HOL guarantees that theorems do indeed hold
- However, does the theorem mean what you think it does?
- you can separate your development in
  - main theorems you care for
  - auxiliary stuff used to derive your main theorems
- it is essential to understand your main theorems

## Importance of Good Definitions — Clarity II

### Guarded by HOL

- proofs checked
- internal, technical definitions
- technical lemmata
- proof tools

#### Manual review needed for

- meaning of main theorems
- meaning of definitions used by main theorems
- meaning of types used by main theorems

### Importance of Good Definitions — Clarity III

- it is essential to understand your main theorems
  - you need to understand all the definitions directly used
  - you need to understand the indirectly used ones as well
  - you need to convince others that you express the intended statement
  - therefore, it is vital to use very simple, clear definitions
- defining concepts is often the main development task
- checking resulting model against real artefact is vital
  - testing via e. g. EVAL
  - formal sanity
  - conformance testing
- wrong models are main source of error when using HOL
- proofs, auxiliary lemmata and auxiliary definitions
  - can be as technical and complicated as you like
  - correctness is guaranteed by HOL
  - reviewers don't need to care

## Importance of Good Definitions — Proofs

- good definitions can shorten proofs significantly
- they improve maintainability
- they can improve automation drastically
- unluckily for proofs definitions often need to be technical
- this contradicts clarity aims

## How to come up with good definitions

- unluckily, it is hard to state what a good definition is
- it is even harder to come up with them
  - there are often many competing interests
  - ▶ a lot of experience and detailed tool knowledge is needed
  - much depends on personal style and taste
- general advice: use more than one definition
  - ▶ in HOL you can derive equivalent definitions as theorems
  - define a concept as clearly and easily as possible
  - derive equivalent definitions for various purposes
    - ★ one very close to your favourite textbook
    - ★ one nice for certain types of proofs
    - ★ another one good for evaluation
    - **\*** ...
- lessons from functional programming apply

# Good Definitions in Functional Programming

### **Objectives**

- clarity (readability, maintainability)
- performance (runtime speed, memory usage, ...)

#### General Advice

- use the powerful type-system
- use many small function definitions
- encode invariants in types and function signatures

## Good Definitions - no number encodings

- KTH VETENDRAP OCH KONST
- many programmers familiar with C encode everything as a number
- enumeration types are very cheap in SML and HOL
- use them instead

### Example Enumeration Types

In C the result of an order comparison is an integer with 3 equivalence classes: 0, negative and positive integers. In SML and HOL, it is better to use a variant type.

```
val _ = Datatype 'ordering = LESS | EQUAL | GREATER';
val compare_def = Define '
   (compare LESS  lt eq gt = lt)
/\ (compare EQUAL lt eq gt = eq)
/\ (compare GREATER lt eq gt = gt) ';
val list_compare_def = Define '
   (list_compare cmp [] [] = EQUAL) /\ (list_compare cmp [] 12 = LESS)
/\ (list_compare cmp l1 [] = GREATER)
/\ (list_compare cmp (x::11) (y::12) = compare (cmp (x:'a) y)
     (* x<y *) LESS
     (* x=y *) (list_compare cmp 11 12)
     (* x>y *) GREATER) ';
```

## Good Definitions — Isomorphic Types

- the type-checker is your friend
  - it helps you find errors
  - code becomes more robust
  - using good types is a great way of writing self-documenting code
- therefore, use many types
- even use types isomorphic to existing ones

### Virtual and Physical Memory Addresses

Virtual and physical addresses might in a development both be numbers. It is still nice to use separate types to avoid mixing them up.

```
val _ = Datatype 'vaddr = VAddr num';
val _ = Datatype 'paddr = PAddr num';

val virt_to_phys_addr_def = Define '
  virt_to_phys_addr (VAddr a) = PAddr( translation of a )';
```

## Good Definitions — Record Types I

- often people use tuples where records would be more appropriate
- using large tuples quickly becomes awkward
  - it is easy to mix up order of tuple entries
    - ⋆ often types coincide, so type-checker does not help
  - no good error messages for tuples
    - ★ hard to decipher type mismatch messages for long product types
    - ★ hard to figure out which entry is missing at which position
    - ★ non-local error messages
    - ★ variable in last entry can hide missing entries
- records sometimes require slightly more proof effort
- however, records have many benefits

## Good Definitions — Record Types II

- using records
  - introduces field names
  - provides automatically defined accessor and update functions
  - leads to better type-checking error messages
- records improve readability
  - accessors and update functions lead to shorter code
  - field names act as documentation
- records improve maintainability
  - improved error messages
  - much easier to add extra fields

## Good Definitions — Encoding Invariants

- try to encode as many invariants as possible in the types
- this allows the type-checker to ensure them for you
- you don't have to check them manually any more
- your code becomes more robust and clearer

### Network Connections (Example by Yaron Minsky from Jane Street)

Consider the following datatype for network connections. It has many implicit invariants.

# Good Definitions — Encoding Invariants II

## Network Connections (Example by Yaron Minsky from Jane Street) II

```
The following definition of connection_info makes the invariants explicit:
type connected = { last_ping : (time * int) option,
                     session_id : string };
type disconnected = { when_disconnected : time };
type connecting = { when_initiated : time };
datatype connection_state =
  Connected of connected
 Disconnected of disconneted
| Connecting of connecting;
type connection_info = {
 state : connection_state,
 server : inet_address
}
```

#### Good Definitions in HOL

## **Objectives**

- clarity (readability)
- good for proofs
- performance (good for automation, easily evaluatable, ...)

#### General Advice

- same advice as for functional programming applies
- use even smaller definitions
  - introduce auxiliary definitions for important function parts
  - use extra definitions for important constants
  - **.**..
- tiny definitions
  - allow keeping proof state small by unfolding only needed ones
  - allow many small lemmata
  - improve maintainability

#### Good Definitions in HOL II

#### Technical Issues

- write definition such that they work well with HOL's tools
- this requires you to know HOL well
- a lot of experience is required
- general advice
  - avoid explicit case-expressions
  - prefer curried functions

## Example

#### Good Definitions in HOL III

#### Multiple Equivalent Definitions

- satisfy competing requirements by having multiple equivalent definitions
- derive them as theorems
- initial definition should be as clear as possible
  - clarity allows simpler reviews
  - simplicity reduces the likelihood of errors

#### Example - ALL\_DISTINCT

## Formal Sanity

#### Formal Sanity

- to ensure correctness test your definitions via e.g. EVAL
- in HOL testing means symbolic evaluation, i.e. proving lemmata
- formally proving sanity check lemmata is very beneficial
  - they should express core properties of your definition
  - thereby they check your intuition against your actual definitions
  - these lemmata are often useful for following proofs
  - using them improves robustness and maintainability of your development
- I highly recommend using formal sanity checks

## Formal Sanity Example I

```
> val ALL_DISTINCT = Define '
   (ALL_DISTINCT [] = T) /\
   (ALL_DISTINCT (h::t) = ~MEM h t /\ ALL_DISTINCT t)';
```

## Example Sanity Check Lemmata

## Formal Sanity Example II 1

```
> val ZIP_def = Define '
    (ZIP [] ys = []) /\ (ZIP xs [] = []) /\
    (ZIP (x::xs) (y::ys) = (x, y)::(ZIP xs ys))'

val ZIP_def =
|- (!ys. ZIP [] ys = []) /\ (!v3 v2. ZIP (v2::v3) [] = []) /\
    (!ys y xs x. ZIP (x::xs) (y::ys) = (x,y)::ZIP xs ys)
```

- above definition of ZIP looks straightforward
- small changes cause heuristics to produce different theorems
- use formal sanity lemmata to compensate

## Formal Sanity Example II 2

```
Example Formal Sanity Lemmata
```

- in your proofs use sanity lemmata, not original definition
- this makes your development robust against
  - small changes to the definition required later
  - changes to Define and its heuristics
  - bugs in function definition package

## Part XII

# Deep and Shallow Embeddings

## Deep and Shallow Embeddings

- often one models some kind of formal language
- important design decision: use deep or shallow embedding
- in a nutshell:
  - shallow embeddings just model semantics
  - deep embeddings model syntax as well
- a shallow embedding directly uses the HOL logic
- a deep embedding
  - defines a datatype for the syntax of the language
  - provides a function to map this syntax to a semantic

## Example: Embedding of Propositional Logic I

- propositional logic is a subset of HOL
- a shallow embedding is therefore trivial

## Example: Embedding of Propositional Logic II

- we can also define a datatype for propositional logic
- this leads to a deep embedding

```
val _ = Datatype 'bvar = BVar num'
val _ = Datatype 'prop = d_true | d_var bvar | d_not prop
                        | d_and prop prop | d_or prop prop
                        | d_implies prop prop';
val _ = Datatype 'var_assignment = BAssign (bvar -> bool)'
val VAR_VALUE_def = Define 'VAR_VALUE (BAssign a) v = (a v)'
val PROP_SEM_def = Define '
  (PROP SEM a d true = T) /\
  (PROP_SEM a (d_var v) = VAR_VALUE a v) /\
  (PROP\_SEM \ a \ (d\_not \ p) = \sim (PROP\_SEM \ a \ p)) / 
  (PROP_SEM a (d_and p1 p2) = (PROP_SEM a p1 /\ PROP_SEM a p2)) /\
  (PROP_SEM a (d_or p1 p2) = (PROP_SEM a p1 \/ PROP_SEM a p2)) /\
  (PROP_SEM a (d_implies p1 p2) = (PROP_SEM a p1 ==> PROP_SEM a p2))'
```

## Shallow vs. Deep Embeddings

#### Shallow

- quick and easy to build
- extensions are simple

### Deep

- can reason about syntax
- allows verified implementations
- sometimes tricky to define
  - e.g. bound variables

## Important Questions for Deciding

- Do I need to reason about syntax?
- Do I have hard to define syntax like bound variables?
- How much time do I have?

## Example: Embedding of Propositional Logic III

- with deep embedding one can easily formalise syntactic properties like
  - Which variables does a propositional formula contain?
  - ► Is a formula in negation-normal-form (NNF)?
- with shallow embeddings
  - syntactic concepts can't be defined in HOL
  - however, they can be defined in SML
  - no proofs about them possible

```
val _ = Define '
  (IS_NNF (d_not d_true) = T) /\ (IS_NNF (d_not (d_var v)) = T) /\
  (IS_NNF (d_not _) = F) /\
  (IS_NNF d_true = T) /\ (IS_NNF (d_var v) = T) /\
  (IS_NNF (d_and p1 p2) = (IS_NNF p1 /\ IS_NNF p2)) /\
  (IS_NNF (d_or p1 p2) = (IS_NNF p1 /\ IS_NNF p2)) /\
  (IS_NNF (d_implies p1 p2) = (IS_NNF p1 /\ IS_NNF p2))'
```

## Verified vs. Verifying Program

#### Verified Programs

- are formalised in HOL
- their properties have been proven once and for all
- all runs have proven properties
- are usually less sophisticated, since they need verification
- is what one wants ideally
- often require deep embedding

## Verifying Programs

- are written in meta-language
- they produce a separate proof for each run
- only certain that current run has properties
- allow more flexibility, e. g. fancy heuristics
- good pragmatic solution
- shallow embedding fine

# Summary Deep vs. Shallow Embeddings

- deep embeddings require more work
- they however allow reasoning about syntax
  - induction and case-splits possible
  - a semantic subset can be carved out syntactically
- syntax sometimes hard to define for deep embeddings
- combinatations of deep and shallow embeddings common
  - certain parts are deeply embedded
  - others are embedded shallowly

# Part XIII

# Rewriting

## Rewriting in HOL

- simplification via rewriting was already a strength of Edinburgh LCF
- it was further improved for Cambridge LCF
- HOL inherited this powerful rewriter
- equational reasoning is still the main workhorse
- there are many different equational reasoning tools in HOL
  - Rewrite library inherited from Cambridge LCF you have seen it in the form of REWRITE\_TAC
  - computeLib fast evaluation build for speed, optimised for ground terms seen in the form of EVAL
  - simpLib Simplification sophisticated rewrite engine, HOL's main workhorse not discussed in this lecture, yet

#### Semantic Foundations

we have seen primitive inference rules for equality before

- these rules allow us to replace any subterm with an equal one
- this is the core of rewriting

#### Conversions

- in HOL, equality reasoning is implemented by conversions
- a conversion is a SML function of type term -> thm
- given a term t, a conversion
  - produces a theorem of the form |- t = t'
  - raises an UNCHANGED exception or
  - ▶ fails, i. e. raises an HOL\_ERR exception

## Example

```
> BETA_CONV ''(\x. SUC x) y''
val it = |- (\x. SUC x) y = SUC y

> BETA_CONV ''SUC y''
Exception-HOL_ERR ... raised

> REPEATC BETA_CONV ''SUC y''
Exception- UNCHANGED raised
```

#### Conversionals

- similar to tactics and tacticals there are conversionals for conversions
- conversionals allow building conversions from simpler ones
- there are many of them
  - ► THENC
  - ORELSEC
  - REPEATC
  - ► TRY\_CONV
  - ► RAND\_CONV
  - ► RATOR CONV
  - ► ABS\_CONV

## Depth Conversionals

- for rewriting depth-conversionals are important
- a depth-conversional applies a conversion to all subterms
- there are many different ones
  - ONCE\_DEPTH\_CONV c top down, applies c once at highest possible positions in distinct subterms
  - ▶ TOP\_SWEEP\_CONV c top down, like ONCE\_DEPTH\_CONV, but continues processing rewritten terms
  - ► TOP\_DEPTH\_CONV c top down, like TOP\_SWEEP\_CONV, but try top-level again after change
  - DEPTH\_CONV c bottom up, recurse over subterms, then apply c repeatedly at top-level
  - ▶ REDEPTH\_CONV c bottom up, like DEPTH\_CONV, but revisits subterms

#### REWR CONV

- it remains to rewrite terms at top-level
- this is achieved by REWR\_CONV
- given a term t and a theorem |- t1 = t2, REWR\_CONV t thm
  - searches an instantiation of term and type variables such that t1 becomes α-equivalent to t
  - fails, if no instantiation is found
  - ▶ otherwise, instantiate the theorem and get |- t1' = t2'
  - ▶ return theorem |- t = t2'

```
Example
```

```
term LENGTH [1;2;3], theorem |- LENGTH ((x:'a)::xs) = SUC (LENGTH xs) found type instantiation: ['':'a'' |-> '':num''] found term instantiation: [''x:num'' |-> ''1''; ''xs'' |-> ''[2;3]''] returned theorem: |- LENGTH [1;2;3] = SUC (LENGTH [2;3])
```

- the tricky part is finding the instantiation
- this problem is called the (term) matching problem

## Term Matching

- given term t\_org and a term t\_goal try to find
  - type substitution ty\_s
  - ▶ term substitution tm\_s
- such that subst tm\_s (inst ty\_s t\_org)  $\stackrel{\alpha}{\equiv}$  t\_goal
- this can be easily implemented by a recursive search

t_org	t_goal	action
t1_org t2_org	t1_goal t2_goal	recurse
t1_org t2_org	otherwise	fail
\x. t_org x	\y. t_goal y	match types of $x$ , $y$ and recurse
\x. t_org x	otherwise	fail
const	same const	match types
const	otherwise	fail
var	anything	try to bind var,
		take care of existing bindings

## **Examples Term Matching**

```
t_goal
                                   substs
t_org
LENGTH ((x:'a)::xs)
                LENGTH [1:2:3]
                                   'a \rightarrow num. x \rightarrow 1. xs \rightarrow [2:3]
∏:'a list
                ∏:'b list
                                   a \rightarrow b
                                   empty substitution
               (P (x:'a) ==> Q) /  T b \rightarrow P x ==> Q
b /\ T
b /\ b
             P x /\ P x
                                   b \rightarrow P x
                                  fail
b /\ b
               Px/\Pv
!x:num. P x / Q x !y. (y = 2) / Q y fail
```

- it is often very annoying that the last match fails
- it prevents us for example rewriting !y. (2 = y) /\ Q y to (!y. (2=y)) /\ (!y. Q y)
- Can we do better? Yes, with higher order (term) matching.

# Higher Order Term Matching

- term matching searches for substitutions such that t\_org becomes  $\alpha$ -equivalent to t\_goal
- higher order term matching searches for substitutions such that t\_org becomes t\_subst such that the  $\beta\eta$ -normalform of t\_subst is  $\alpha$ -equivalent equivalent to  $\beta\eta$ -normalform of t\_goal, i.e.

higher order term matching is aware of the semantics of  $\lambda$ 

```
\beta-reduction (\lambda x. f) y = f[y/x]
\eta-conversion (\lambda x. f x) = f where x is not free in f
```

- the HOL implementation expects t\_org to be a higher-order pattern
  - t\_org is β-reduced
  - ▶ if X is a variable that should be instantiated, then all arguments should be distinct variables
- for other forms of t\_org, HOL's implementation might fail
- higher order matching is used by HO\_REWR\_CONV

# Examples Higher Order Term Matching

t_org	t_goal	substs
!x:num. P x /\ Q x	!y. $(y = 2) / Q' y$	$P \rightarrow (y. y = 2), Q \rightarrow Q$
!x. P x /\ Q x	!x. P x /\ Q x /\ Z x	Q $\rightarrow$ \x. Q x /\ Z x
!x. P x /\ Q	!x. P x /\ Q x	fails
!x. P (x, x)	!x. Q x	fails
!x. P (x. x)	!x. FST (x.x) = SND (x.x)	$P \rightarrow \xx$ . FST $xx = SND xx$

Don't worry, it might look complicated, but in practice it is easy to get a feeling for higher order matching.

## Rewrite Library

- the rewrite library combines REWR\_CONV with depth conversions
- there are many different conversions, rules and tactics
- at they core, they all work very similarly
  - given a list of theorems, a set of rewrite theorems is derived
    - \* split conjunctions
    - ★ remove outermost universal quantification
    - ★ introduce equations by adding = T (or = F) if needed
  - REWR\_CONV is applied to all the resulting rewrite theorems
  - a depth-conversion is used with resulting conversion
- for performance reasons an efficient indexing structure is used
- by default implicit rewrites are added

## Rewrite Library II

- REWRITE CONV
- REWRITE\_RULE
- REWRITE\_TAC
- ASM\_REWRITE\_TAC
- ONCE\_REWRITE\_TAC
- PURE\_REWRITE\_TAC
- PURE\_ONCE\_REWRITE\_TAC
- . . .

## Ho\_Rewrite Library

- similar to Rewrite lib, but uses higher order matching
- internally uses HO\_REWR\_CONV
- similar conversions, rules and tactics as Rewrite lib
  - ► Ho\_Rewrite.REWRITE\_CONV
  - ► Ho\_Rewrite.REWRITE\_RULE
  - ► Ho\_Rewrite.REWRITE\_TAC
  - ► Ho\_Rewrite.ASM\_REWRITE\_TAC
  - ► Ho Rewrite.ONCE REWRITE TAC
  - ► Ho\_Rewrite.PURE\_REWRITE\_TAC
  - ► Ho\_Rewrite.PURE\_ONCE\_REWRITE\_TAC

## Examples Rewrite and Ho\_Rewrite Library

```
> REWRITE_CONV [LENGTH] ''LENGTH [1;2]''
val it = |- LENGTH [1: 2] = SUC (SUC 0)
> ONCE_REWRITE_CONV [LENGTH] ''LENGTH [1:2]''
val it = |- LENGTH [1: 2] = SUC (LENGTH [2])
> REWRITE_CONV [] ''A /\ A /\ ~A''
Exception- UNCHANGED raised
> PURE_REWRITE_CONV [NOT_AND] ''A /\ A /\ ~A''
val it = |-A / A / ~A <=> A / F
> REWRITE_CONV [NOT_AND] ''A /\ A /\ ~A''
val it = |-A / A / \sim A <=> F
> REWRITE_CONV [FORALL_AND_THM] ''!x. P x /\ Q x /\ R x''
Exception- UNCHANGED raised
> Ho_Rewrite.REWRITE_CONV [FORALL_AND_THM] ''!x. P x /\ Q x /\ R x''
val it = |-|x. Px| / Qx / Rx  <=> (|x. Px) / (|x. Qx) / (|x. Rx)
```

## Summary Rewrite and Ho\_Rewrite Library

- the Rewrite and Ho\_Rewrite library provide powerful infrastructure for term rewriting
- thanks to clever implementations they are reasonably efficient
- basics are easily explained
- however, efficient usage needs some experience

## Term Rewriting Systems

- to use rewriting efficiently, one needs to understand about term rewriting systems
- this is a large topic
- one can easily give whole course just about term rewriting systems
- however, in practise you quickly get a feeling
- important points in practise
  - ensure termination of your rewrites
  - make sure they work nicely together

## Term Rewriting Systems — Termination

## Theory

- choose well-founded order ≺
- for each rewrite theorem |-t1| = t2 ensure t2 < t1

#### **Practice**

- informally define for yourself what **simpler** means
- ensure each rewrite makes terms simpler
- good heuristics
  - subterms are simpler than whole term
  - use an order on functions

## Termination — Subterm examples

- a proper subterm is always simpler
  - ▶ !1. APPEND [] 1 = 1

  - ▶ !1. REVERSE (REVERSE 1) = 1
  - ▶ !t1 t2. if T then t1 else t2 <=> t1
  - $\triangleright$  !n. n \* 0 = 0
- the right hand side should not use extra vars, throwing parts away is usually simpler
  - ▶ !x xs. (SNOC x xs = []) = F
  - ▶ !x xs. LENGTH (x::xs) = SUC (LENGTH xs)
  - ▶ !n x xs. DROP (SUC n) (x::xs) = DROP n xs

## Termination — use simpler terms

- it is useful to consider some functions simple and other complicated
- replace complicated ones with simple ones
- never do it in the opposite direction
- clear examples

```
    |- !m n. MEM m (COUNT_LIST n) <=> (m < n)</li>
    |- !ls n. (DROP n ls = []) <=> (n >= LENGTH ls)
```

- unclear example
  - ► |- !L. REVERSE L = REV L []

#### Termination — Normalforms

- some equations can be used in both directions
- one should decide on one direction
- this implicitly defined a normalform one wants terms to be in
- examples
  - ► |- !f 1. MAP f (REVERSE 1) = REVERSE (MAP f 1)
  - ▶ |- !11 12 13. 11 ++ (12 ++ 13) = 11 ++ 12 ++ 13

#### Termination — Problematic rewrite rules

some equations immediately lead to non-termination, e.g.

```
▶ |-|m| n. m + n = n + m
▶ |-|m| m = m + 0
```

slightly more subtle are rules like

```
▶ |-!n. fact n = if (n = 0) then 1 else n * fact(n-1)
```

 often combination of multiple rules leads to non-termination this is especially problematic when adding to predefined set of rewrites

```
▶ |-!m n p. m + (n + p) = (m + n) + p and
|-!m n p. (m + n) + p = m + (n + p)
```

# Rewrites working together

- rewrite rules should not complete with each other
- if a term ta can be rewritten to ta1 and ta2 applying different rewrite rules, then the ta1 and ta2 should be further rewritten to a common tb
- this can often be achieved by adding extra rewrite rules

## Example

Assume we have the rewrite rules  $|-DOUBLE \ n = n + n$  and  $|-EVEN \ (DOUBLE \ n) = T$ .

With these the term EVEN (DOUBLE 2) can be rewritten to

- T or
- EVEN (2 + 2).

To avoid a hard to predict result, EVEN (2+2) should be rewritten to T. Adding an extra rewrite rule |-| EVEN (n + n) = T achieves this.

## Rewrites working together II

- to design rewrite systems that work well, normalforms are vital
- a term is in normalform, if it cannot be rewritten any further
- one should have a clear idea what the normalform of common terms looks like
- all rules should work together to establish this normalform
- the right-hand-side of each rule should be in normalform
- the left-hand-side should not be simplifiable by any other rule
- the order in which rules are applied should not influence the final result

### computeLib

- computeLib is the library behind EVAL
- it is a rewriting library designed for evaluating ground terms (i. e. terms without variables) efficiently
- it uses a call-by-value strategy similar to SML's
- it uses first order term matching
- ullet it performs eta reduction in addition to rewrites

### compset

- computeLib uses compsets to store its rewrites
- a compset stores
  - rewrite rules
  - extra conversions
- the extra conversions are guarded by a term pattern for efficiency
- users can define their own compsets
- however, computeLib maintains one special compset called the\_compset
- the\_compset is used by EVAL

#### **EVAL**

- EVAL uses the\_compset
- tools like the Datatype of TFL automatically extend the\_compset
- this way, EVAL knows about (nearly) all types and functions
- one can extended the\_compset manually as well
- rewrites exported by Define are good for ground terms but may lead to non-termination for non-ground terms
- zDefine prevents TFL from automatically extending the\_compset

### simpLib

- simpLib is a sophisticated rewrite engine
- it is HOL's main workhorse
- it provides
  - higher order rewriting
  - usage of context information
  - conditional rewriting
  - arbitrary conversions
  - support for decision procedures
  - simple heuristics to avoid non-termination
  - fancier preprocessing of rewrite theorems
  - · ...
- it is very powerful, but compared to Rewrite lib sometimes slow

# Basic Usage I

- simpLib uses simpsets
- simpsets are special datatypes storing
  - rewrite rules
  - conversions
  - decision procedures
  - congruence rules
  - **•** . . .
- in addition there are simpset-fragments
- simpset-fragments contain similar information as simpsets
- fragments can be added to and removed from simpsets
- common usage: basic simpset combined with one or more simpset-fragments, e. g.

```
 list_ss ++ pairSimps.gen_beta_ss
   std_ss ++ QI_ss
```

**.** . . .

# Basic Usage II

- a call to the simplifier takes as arguments
  - a simpset
  - ▶ a list of rewrite theorems
- common high-level entry points are
  - ▶ SIMP\_CONV ss thmL conversion
  - ► SIMP\_RULE ss thmL rule
  - ► SIMP\_TAC ss thmL tactic without considering assumptions
  - ► ASM\_SIMP\_TAC ss thmL tactic using assumptions to simplify goal
  - ► FULL\_SIMP\_TAC ss thmL tactic simplifying assumptions with each other and goal with assumptions
  - REV\_FULL\_SIMP\_TAC ss thmL similar to FULL\_SIMP\_TAC but with reversed order of assumptions
- there are many derived tools not discussed here

## Basic Simplifier Examples

```
> SIMP_CONV bool_ss [LENGTH] "LENGTH [1;2]"
val it = |- LENGTH [1; 2] = SUC (SUC 0)
> SIMP_CONV std_ss [LENGTH] "LENGTH [1;2]"
val it = |- LENGTH [1; 2] = 2
> SIMP_CONV list_ss [] "LENGTH [1;2]"
val it = |- LENGTH [1; 2] = 2
```

## FULL\_SIMP\_TAC Example

### Current GoalStack

P (SUC (SUC x0)) (SUC (SUC y0))

- 0. SUC y1 = y2
- 1. x1 = SUC x0
- 2. y1 = SUC y0
- 3. SUC x1 = x2

#### Action

FULL\_SIMP\_TAC std\_ss []

#### Resulting GoalStack

P (SUC (SUC x0)) y2

- 0. SUC (SUC y0) = y2
- 1. x1 = SUC x0
- 2. y1 = SUC y0
- 3. SUC x1 = x2

## REV\_FULL\_SIMP\_TAC Example

#### Current GoalStack

P (SUC (SUC x0)) y2

- 0. SUC (SUC y0) = y2
- 1. x1 = SUC x0
- 2. y1 = SUC y0
- 3. SUC x1 = x2

#### Action

REV\_FULL\_SIMP\_TAC std\_ss []

### Resulting GoalStack

#### P x2 y2

-----

- 0. SUC (SUC y0) = y2
- 1. x1 = SUC x0
- 2. y1 = SUC y0
- 3. SUC (SUC x0) = x2

## Common simpsets

- pure\_ss empty simpset
- bool\_ss basic simpset
- std\_ss standard simpset
- arith\_ss arithmetic simpset
- list\_ss list simpset
- real\_ss real simpset

# Common simpset-fragments

- many theories and libraries provide their own simpset-fragments
- PRED\_SET\_ss simplify sets
- STRING\_ss simplify strings
- QI\_ss extra quantifier instantiations
- gen\_beta\_ss  $\beta$  reduction for pairs
- ETA\_ss  $\eta$  conversion
- EQUIV\_EXTRACT\_ss extract common part of equivalence
- CONJ\_ss use conjunctions for context
- . . .

#### Build-In Conversions and Decision Procedures

- in contrast to Rewrite lib the simplifier can run arbitrary conversions
- most useful is probably  $\beta$  reduction
- std\_ss has support for basic arithmetic and numerals
- it also has simple, syntactic conversions for instantiating quantifiers

```
▶ !x. ... /\ (x = c) /\ ... ==> ...

▶ !x. ... \/ ~(x = c) \/ ...

▶ ?x. ... /\ (x = c) /\ ...
```

- besides very useful conversions, there are decision procedures as well
- the most frequently used one is probably the arithmetic decision procedure you already know from DECIDE

## Examples I

```
> SIMP_CONV std_ss [] ''(\x. x + 2) 5''
val it = |- (\x. x + 2) 5 = 7

> SIMP_CONV std_ss [] ''!x. Q x /\ (x = 7) ==> P x''
val it = |- (!x. Q x /\ (x = 7) ==> P x) <=> (Q 7 ==> P 7)''

> SIMP_CONV std_ss [] ''?x. Q x /\ (x = 7) /\ P x''
val it = |- (?x. Q x /\ (x = 7) /\ P x) <=> (Q 7 /\ P 7)''

> SIMP_CONV std_ss [] ''x > 7 ==> x > 5''
Exception- UNCHANGED raised

> SIMP_CONV arith_ss [] ''x > 7 ==> x > 5''
val it = |- (x > 7 ==> x > 5) <=> T
```

# Higher Order Rewriting

- the simplifier supports higher order rewriting
- this is often very handy
- for example it allows moving quantifiers around easily

## Examples

#### Context

- a great feature of the simplifier is that it can use context information
- by default simple context information is used like
  - the precondition of an implication
  - ▶ the condition of if-then-else
- one can configure which context to use via congruence rules
  - ▶ by using CONJ\_ss one can easily use context of conjunctions
  - warning: using CONJ\_ss can be slow
  - using other contexts is outside the scope of this lecture
- using context often simplifies proofs drastically
  - using Rewrite lib, often a goal needs to be split and a precondition moved to the assumptions
  - ▶ then ASM\_REWRITE\_TAC can be used
  - with SIMP\_TAC there is no need to split the goal

### Context Examples

# Conditional Rewriting I

- perhaps the most powerful feature of the simplifier is that it supports conditional rewriting
- this means it allows conditional rewrite theorems of the form
   |- cond ==> (t1 = t2)
- if the simplifier finds a term t1' it can rewrite via t1 = t2 to t2', it tries to discharge the assumption cond'
- for this, it calls itself recursively on cond'
  - all the decision procedures and all context information is used
  - conditional rewriting can be used
  - ▶ to prevent divergence, there is a limit on recursion depth
- if cond' = T can be shown, t1' is rewritten to t2'
- otherwise t1' is not modified

# Conditional Rewriting Example

consider the conditional rewrite theorem

```
!1 n. LENGTH 1 <= n ==> (DROP n 1 = [])
```

let's assume we want to prove

```
(DROP 7 [1;2;3;4]) ++ [5;6;7] = [5;6;7]
```

- we can without conditional rewriting
  - ▶ show |- LENGTH [1;2;3;4] <= 7
  - use this to discharge the precondition of the rewrite theorem
  - use the resulting theorem to rewrite the goal
- with conditional rewriting, this is all automated

conditional rewriting often shortens proofs considerably

# Conditional Rewriting Example II

### Proof with Rewrite

```
prove (''(DROP 7 [1;2;3;4]) ++ [5;6;7] = [5;6;7]'',
'DROP 7 [1;2;3;4] = []' by (
    MATCH_MP_TAC DROP_LENGTH_TOO_LONG >>
    REWRITE_TAC[LENGTH] >>
    DECIDE_TAC
) >>
ASM_REWRITE_TAC[APPEND])
```

## Proof with Simplifier

```
prove (''(DROP 7 [1;2;3;4]) ++ [5;6;7] = [5;6;7]'',
ASM_SIMP_TAC list_ss [])
```

# Conditional Rewriting II

- conditional rewriting is a very powerful technique
- decision procedures and sophisticated rewrites can be used to discharge preconditions without cluttering proof state
- it provides a powerful search for theorems that apply
- however, if used naively, it can be slow
- moreover, to work well, rewrite theorems need to of a special form

# Conditional Rewriting Pitfalls I

- if the pattern is too general, the simplifier becomes very slow
- consider the following, trivial but hopefully useful example

```
Looping example

> val my_thm = prove (''^P ==> (P = F)'', PROVE_TAC[])

> time (SIMP_CONV std_ss [my_thm]) ''P1 /\ P2 /\ P3 /\ ... /\ P10''
runtime: 0.84000s, gctime: 0.02400s, systime: 0.02400s.

Exception- UNCHANGED raised

> time (SIMP_CONV std_ss []) ''P1 /\ P2 /\ P3 /\ ... /\ P10''
runtime: 0.00000s, gctime: 0.00000s, systime: 0.00000s.

Exception- UNCHANGED raised
```

- notice that the rewrite is applied at plenty of places (quadratic in number of conjuncts)
- notice that each backchaining triggers many more backchainings
- each has to be aborted to prevent diverging
- as a result, the simplifier becomes very slow
- ▶ incidentally, the conditional rewrite is useless

# Conditional Rewriting Pitfalls II

- good conditional rewrites |- c ==> (1 = r) should mention only variables in c that appear in 1
- ullet if c contains extra variables x1 ... xn, the conditional rewrite engine has to search instantiations for them
- this mean that conditional rewriting is trying discharge the precondition ?x1 ... xn. c
- the simplifier is usually not able to find such instances

```
Transitivity
```

```
> val P_def = Define 'P x y = x < y';
> val my_thm = prove (''!x y z. P x y ==> P y z ==> P x z'', ...)
> SIMP_CONV arith_ss [my_thm] ''P 2 3 /\ P 3 4 ==> P 2 4''
Exception- UNCHANGED raised

(* However transitivity of < build in via decision procedure *)
> SIMP_CONV arith_ss [P_def] ''P 2 3 /\ P 3 4 ==> P 2 4''
val it = |- P 2 3 /\ P 3 4 ==> P 2 4 <=> T:
```

## Conditional Rewriting Pitfalls III

let's look in detail why SIMP\_CONV did not make progress above

```
> set_trace "simplifier" 2;
> SIMP_CONV arith_ss [my_thm] ''P 2 3 /\ P 3 4 ==> P 2 4''
[468000]: more context: |-!x y z. P x y ==> P y z ==> P x z
[468000]: New rewrite: |-(?y. P x y / V y z) ==> (P x z <=> T)
           more context: [.] |- P 2 3 /\ P 3 4
[584000]:
[584000]:
           New rewrite: [.] |- P 2 3 <=> T
           New rewrite: [.] |- P 3 4 <=> T
[584000]:
[588000]:
           rewriting P 2 4 with |-(?y. P x y / P y z) ==> (P x z <=> T)
[588000]:
           trying to solve: ?y. P 2 y /\ P y 4
[588000]:
           rewriting P 2 y with |-(?y. P x y / P y z) ==> (P x z <=> T)
[592000]:
           trying to solve: ?y'. P 2 y' /\ P y' y
. . .
[596000]:
           looping - cut
[608000]:
           looping - stack limit reached
. . .
[640000]: couldn't solve: ?y. P 2 y /\ P y 4
Exception- UNCHANGED raised
```

#### Conditional vs. Unconditional Rewrite Rules

- conditional rewrite rules are often much more powerful
- however, Rewrite lib does not support them
- for this reason there are often two versions of rewrite theorems

### drop example

DROP\_LENGTH\_NIL is a useful rewrite rule:

```
|-!1. DROP (LENGTH 1) 1 = []
```

- in proofs, one needs to be careful though to preserve exactly this form
  - one should not (partly) evaluate LENGTH 1 or modify 1 somehow
- with the conditional rewrite rule DROP\_LENGTH\_TOO\_LONG one does not need to be as careful

```
|-!1 \text{ n. LENGTH } 1 \le n ==> (DROP \text{ n } 1 = [])
```

the simplifier can use simplify the precondition using information about LENGTH and even arithmetic decision procedures

## Special Rewrite Forms

- some theorems given in the list of rewrites to the simplifier are used for special purposes
- there are marked functions that mark these theorems
  - ▶ Once : thm → thm use given theorem at most once
  - ▶ Ntimes : thm → int → thm use given theorem at most the given number of times
  - ► AC : thm -> thm -> thm use given associativity and commutativity theorems for AC rewriting
  - ▶ Cong : thm → thm use given theorem as a congruence rule
- these special forms are easy ways to add this information to a simpset
- it can be directly set in a simpset as well

## Example Once

```
> SIMP_CONV pure_ss [Once ADD_COMM] ''a + b = c + d''
val it = |- (a + b = c + d) <=> (b + a = c + d)
> SIMP_CONV pure_ss [Ntimes ADD_COMM 2] ''a + b = c + d''
val it = |- (a + b = c + d) <=> (a + b = c + d)
> SIMP_CONV pure_ss [ADD_COMM] ''a + b = c + d''
Exception- UNCHANGED raised
> ONCE_REWRITE_CONV [ADD_COMM] ''a + b = c + d''
val it = |- (a + b = c + d) <=> (b + a = d + c)
> REWRITE_CONV [ADD_COMM] ''a + b = c + d''
... diverges ...
```

## Stateful Simpset

- the simpset srw\_ss() is maintained by the system
  - it is automatically extended by new type-definitions
  - theories can extend it via export\_rewrites
  - ▶ libs can augment it via augment\_srw\_ss
- the stateful simpset contains many rewrites
- it is very powerful and easy to use

## Example

```
> SIMP_CONV (srw_ss()) [] ''case [] of [] => (2 + 4)''
val it = |- (case [] of [] => 2 + 4 | v::v1 => ARB) = 6
```

# Discussion on Stateful Simpset

- the stateful simpset is very powerful and easy to use
- however, results are hard to predict
- proofs using it unwisely are hard to maintain
- the stateful simpset can expand too much
  - bigger, harder to read proof states
  - high level arguments become hard to see
- whether to use the stateful simpset depends on personal proof style
- I advise at the beginning to not use srw\_ss
- once you got a good intuition on how the simplifier works, make your own choice

# Adding Own Conversions

- it is complicated to add arbitrary decision procedures to a simpset
- however, adding simple conversions is straightforward
- a conversion is described by a stdconvdata record

use std\_conv\_ss to create simpset-fragement

```
Example
val WORD_ADD_ss =
  simpLib.std_conv_ss
  {conv = CHANGED_CONV WORD_ADD_CANON_CONV,
    name = "WORD_ADD_CANON_CONV",
    pats = [''words$word_add (w:'a word) y'']}
```

# **Summary Simplifier**

- the simplifier is HOL's main workhorse for automation
- it is very powerful
- conditional rewriting very powerful
  - here only simple examples were presented
  - experiment with it to get a feeling
- many advanced features not discussed here at all
  - using congruence rules
  - writing own decision procedures
  - rewriting with respect to arbitrary congruence relations

#### Warning

The simplifier is very powerful. Make sure you understand it and are in control when using it. Otherwise your proofs easily become lengthy, convoluted and hard to maintain.

# Part XIV

# Advanced Definition Principles

#### Relations

- a relation is a function from some arguments to bool
- the following example types are all types of relations:

```
> : 'a -> 'a -> bool
> : 'a -> 'b -> bool
> : 'a -> 'b -> 'c -> 'd -> bool
> : ('a # 'b # 'c) -> bool
> : bool
> : 'a -> bool
```

relations are closely related to sets

```
    ▶ R a b c <=> (a, b, c) IN {(a, b, c) | R a b c}
    ▶ (a, b, c) IN S <=> (\a b c. (a, b, c) IN S) a b c
```

#### Relations II

relations are often defined by a set of rules

#### Definition of Reflexive-Transitive Closure

The transitive reflexive closure of a relation  $R: 'a \rightarrow 'a \rightarrow bool$  can be defined as the least relation RTC R that satisfies the following rules:

- if the rules are monoton, a least and a greatest fix point exists (Knaster-Tarski theorem)
- least fixpoints give rise to inductive relations
- greatest fixpoints give rise to coinductive relations

# (Co)inductive Relations in HOL

- (Co)IndDefLib provides infrastructure for defining (co)inductive relations
- given a set of rules Hol\_(co)reln defines (co)inductive relations
- 3 theorems are returned and stored in current theory
  - ▶ a rules theorem it states that the defined constant satisfies the rules
  - ▶ a cases theorem this is an equational form of the rules showing that the defined relation is indeed a fixpoint
  - ▶ a (co)induction theorem
- additionally a strong (co)induction theorem is stored in current theory

### Example: Transitive Reflexive Closure

### Example: Transitive Reflexive Closure II

```
val RTC_REL_ind = |- !R RTC_REL'.
  ((!x y. R x y ==> RTC_REL' x y) / (!x. RTC_REL' x x) / 
   (!x y z. RTC_REL' x y /\ RTC_REL' y z ==> RTC_REL' x z)) ==>
  (!a0 a1. RTC_REL R a0 a1 ==> RTC_REL' a0 a1)
> val RTC_REL_strongind = DB.fetch "-" "RTC_REL_strongind"
val RTC_REL_strongind = |- !R RTC_REL'.
  (!x y. R x y ==> RTC_REL' x y) / (!x. RTC_REL' x x) / 
  (!x y z.
     RTC_REL R x y /\ RTC_REL' x y /\ RTC_REL R y z /\
     RTC_REL' y z ==>
     RTC REL' x z) ==>
  ( !a0 a1. RTC_REL R a0 a1 ==> RTC_REL' a0 a1)
```

### Example: EVEN

```
> val (EVEN_REL_rules, EVEN_REL_ind, EVEN_REL_cases) = Hol_reln
    '(EVEN_REL 0) /\ (!n. EVEN_REL n ==> (EVEN_REL (n + 2)))';

val EVEN_REL_cases =
    |- !a0. EVEN_REL a0 <=> (a0 = 0) \/ ?n. (a0 = n + 2) /\ EVEN_REL n

val EVEN_REL_rules =
    |- EVEN_REL 0 /\ !n. EVEN_REL n ==> EVEN_REL (n + 2)

val EVEN_REL_ind = |- !EVEN_REL'.
    (EVEN_REL_ind = |- !EVEN_REL' n ==> EVEN_REL' (n + 2))) ==>
    (!a0. EVEN_REL a0 ==> EVEN_REL' a0)
```

- notice that in this example there is exactly one fixpoint
- therefore for these rule, the induction and coinductive relation coincide

### Example: Dummy Relations

```
> val (DF_rules, DF_ind, DF_cases) = Hol_reln
    '(!n. DF (n+1) ==> (DF n))'
> val (DT_rules, DT_coind, DT_cases) = Hol_coreln
    '(!n. DT (n+1) ==> (DT n))'

val DT_coind =
    |- !DT'. (!a0. DT' a0 ==> DT' (a0 + 1)) ==> !a0. DT' a0 ==> DT a0

val DF_ind =
    |- !DF'. (!n. DF' (n + 1) ==> DF' n) ==> !a0. DF a0 ==> DF' a0

val DT_cases = |- !a0. DT a0 <=> DT (a0 + 1):
    val DF_cases = |- !a0. DF a0 <=> DF (a0 + 1):
```

- notice that for both DT and DF we used essentially a non-terminating recursion
- DT is always true, i. e. |- !n. DT n
- DF is always false, i. e. |- !n. ~(DF n)

### **Quotient Types**

- quotientLib allows to define types as quotients of existing types with respect to partial equivalence relation
- each equivalence class becomes a value of the new type
- partiality allows ignoring certain types
- quotientLib allows to lift definitions and lemmata as well
- details are technical and won't be presented here

### Quotient Types Example

- let's assume we have an implementation of finite sets of numbers as binary trees with
  - ▶ type binset
  - binary tree invariant WF\_BINSET : binset -> bool
  - ► constant empty\_binset
  - ▶ add and member functions add : num → binset → binset, mem : binset → num → bool
- we can define a partial equivalence relation by

```
binset_equiv b1 b2 := (
  WF_BINSET b1 /\ WF_BINSET b2 /\
  (!n. mem b1 n <=> mem b2 n))
```

- this allows defining a quotient type of sets of numbers
- functions empty\_binset, add and mem as well as lemmata about them can be lifted automatically

## **Quotient Types Summary**

- quotient types are sometimes very useful
  - e.g. rational numbers are defined as a quotient type
- there is powerful infrastructure for them
- many tasks are automated
- however, the details are technical and won't be discussed here

# Pattern Matching / Case Expressions

- pattern matching ubiquitous in functional programming
- pattern matching is a powerful technique
- it helps to write concise, readable definitions
- very handy and frequently used for interactive theorem proving in higher-order logic (HOL)
- however, it is not directly supported by HOL's logic
- representations in HOL
  - sets of equations as produced by Define
  - decision trees (printed as case-expressions)

### TFL / Define

- we have already used top-level pattern matches with the TFL package
- Define is able to handle them
  - all the semantic complexity is taken care of
  - no special syntax or functions remain
  - no special rewrite rules, reasoning tools needed afterwards
- Define produces a set of equations
- this is the recommended way of using pattern matching in HOL

```
Example
```

### Case Expressions

- sometimes one does not want to use this compilation by TFL
  - ▶ one wants to use pattern-matches somewhere nested in a term
  - one might not want to introduce a new constant
  - one might want to avoid using TFL for technical reasons
- in such situations, case-expressions can be used
- their syntax is similar to the syntax used by SML

### Case Expressions II

- the datatype package define case-constants for each datatype
- the parser contains a pattern compilation algorithm
- case-expressions are by the parser compiled to decision trees using case-constants
- pretty printer prints these decision trees as case-expressions again

### Case Expression Issues

- using case expressions feels very natural to functional programmers
- case-expressions allow concise, well-readable definitions
- however, there are also many drawbacks
- there is large, complicated code in the parser and pretty printer
  - this is outside the kernel
  - lacktriangle parsing a pretty-printed term can result in a non lpha-equivalent one
  - ▶ there are bugs in this code (see e.g. Issue #416 reported 8 May 2017)
- the results are hard to predict
  - heuristics involved in creating decision tree
  - results sometimes hard to predict
  - however, it is beneficial that proofs follow this internal, volatile structure

### Case Expression Issues II

- technical issues
  - it is tricky to reason about decision trees
  - ▶ rewrite rules about case-constants needs to be fetched from TypeBase
    - ★ alternative srw\_ss often does more than wanted
  - partially evaluated decision-trees are not pretty printed nicely any more
- underspecified functions
  - decision trees are exhaustive
  - they list underspecified cases explicitly with value ARB
  - this can be lengthy
  - Define in contrast hides underspecified cases

### Case Expression Example I

### Partial Proof Script

```
val _ = prove (''!11 12.
  (LENGTH 11 = LENGTH 12) ==>
  ((ZIP 11 12 = []) <=> ((11 = []) /\ (12 = [])))'',
ONCE_REWRITE_TAC [ZIP_def]
```

#### Current Goal

## Case Expression Example IIa – partial evaluation

### Partial Proof Script

```
val _ = prove (''!11 12.
  (LENGTH 11 = LENGTH 12) ==>
  ((ZIP 11 12 = []) <=> ((11 = []) /\ (12 = [])))'',

ONCE_REWRITE_TAC [ZIP_def] >>
REWRITE_TAC[pairTheory.pair_case_def] >> BETA_TAC
```

#### Current Goal

# Case Expression Example IIb — following tree structure

### Partial Proof Script

```
val _ = prove (''!11 12.
  (LENGTH 11 = LENGTH 12) ==>
        ((ZIP 11 12 = []) <=> ((11 = []) /\ (12 = [])))'',

ONCE_REWRITE_TAC [ZIP_def] >>
Cases_on '11' >| [
        REWRITE_TAC[listTheory.list_case_def]
```

#### Current Goal

## Case Expression Summary

- case expressions are natural to functional programmers
- they allow concise, readable definitions
- however, fancy parser and pretty-printer needed
  - trustworthiness issues
  - sanity check lemmata advisable
- reasoning about case expressions can be tricky and lengthy
- proofs about case expression often hard to maintain
- therefore, use top-level pattern matching via Define if easily possible

# Part XV

# Maintainable Proofs

#### Motivation

- proofs are hopefully still used in a few weeks, months or even years
- often the environment changes slightly during the lifetime of a proof
  - your definitions change slightly
  - your own lemmata change (e.g. become more general)
  - used libraries change
  - HOL changed
    - ★ automation became more powerful
    - rewrite rules in certain simpsets changed
    - ★ definition packages produce slightly different theorems
    - ★ autogenerated variable-names change
    - \*
- even if HOL and used libraries are stable, proofs often go through several iterations
- often they are adapted by someone else than the original author
- therefore it is important that proofs are easily maintainable

### Nice Properties of Proofs

- maintainability is closely linked to other desirable properties of proofs
  - easily understandable
  - well-structured
  - robust
    - ★ they should be able to scope with minor changes to environment
    - ★ if they fail they should do so at sensible points
  - reusable
- How can one write proofs with such properties?
- as usual, there are no easy answers but plenty of good advice
- I recommend following the advice of ProofStyle manual

## Formatting

- format your proof such that it easily understandable
- make the structure of the proof very clear
- show clearly where subgoals start and stop
- use indentation to mark proofs of subgoals
- use empty lines to separate large proofs of subgoals
- use comments where appropriate

# Formatting Example I

### Bad Example Term Formatting

```
prove (''!11 12. 11 <> [] ==> LENGTH 12 <
LENGTH (11 ++ 12)'',
...)</pre>
```

### Good Example Term Formatting

# Formatting Example II

### Bad Example Subgoals

```
prove (''!11 12. 11 <> [] ==> (LENGTH 12 < LENGTH (11 ++ 12))'',
Cases >>
REWRITE_TAC[] >>
REWRITE_TAC[listTheory.LENGTH, listTheory.LENGTH_APPEND] >>
REPEAT STRIP_TAC >>
DECIDE_TAC)
```

### Improved Example Subgoals

At least show when a subgoal starts and ends

```
prove (''!11 12. 11 <> [] ==> (LENGTH 12 < LENGTH (11 ++ 12))'',
Cases >> (
    REWRITE_TAC[]
) >>
REWRITE_TAC[listTheory.LENGTH, listTheory.LENGTH_APPEND] >>
REPEAT STRIP_TAC >>
DECIDE TAC)
```

# Formatting Example II 2

#### Good Example Subgoals

Make sure REWRITE\_TAC is only applied to first subgoal and proof fails, if it does not solve this subgoal.

```
prove (''!11 12. 11 <> [] ==> (LENGTH 12 < LENGTH (11 ++ 12))'',
Cases >- (
    REWRITE_TAC[] >> )
REWRITE_TAC[listTheory.LENGTH, listTheory.LENGTH_APPEND] >>
REPEAT STRIP_TAC >> DECIDE_TAC)
```

# Formatting Example II 3

#### Alternative Good Example Subgoals

Alternative good formatting using THENL

```
prove (''!11 12. 11 <> [] ==> (LENGTH 12 < LENGTH (11 ++ 12))'',
Cases >| [
    REWRITE_TAC[],

    REWRITE_TAC[listTheory.LENGTH, listTheory.LENGTH_APPEND] >>
    REPEAT STRIP_TAC >>
    DECIDE_TAC
])
```

#### Another Bad Example Subgoals

Bad formatting using THENL

```
prove (''!11 12. 11 <> [] ==> (LENGTH 12 < LENGTH (11 ++ 12))'',
Cases >| [REWRITE_TAC[],
REWRITE_TAC[listTheory.LENGTH, listTheory.LENGTH_APPEND] >>
REPEAT STRIP_TAC >> DECIDE_TAC])
```

#### Some basic advice

- use semicoli after each declaration
  - if exception is raised during interactive processing (e.g. by a failing proof), previous successful declarations are kept
  - ▶ it sometimes leads to better error messages in case of parsing errors
- use plenty of parentheses to make structure very clear
- don't ignore parser warnings
  - especially multiple possible parse trees are likely to lead to unstable proofs
  - understand why such warnings occur and make sure there is no problem
- format your development well
  - use indentation
  - use linebreaks at sensible points
  - don't use overlong lines
  - **.** . . .
- don't use open in middle of files
- personal opinion: avoid unicode in source files

## KISS and Premature Optimisation

- follow standard design principles
  - KISS principle
  - "premature optimization is the root of all evil" (Donald Knuth)
- don't try to be overly clever
- simple proofs are preferable
- proof-checking-speed mostly unimportant
- conciseness not a value in itself but desirable if it helps
  - readability
  - maintainability
- abstraction is often declarable, but also has a price
  - don't use too complex, artificial definitions and lemmata

#### Too much abstraction

#### Too much abstraction Example

```
val ABSTRACT_LEMMA = prove ('
!(size :'a -> num) (P : 'a -> bool) (combine : 'a -> 'a -> 'a).
    (!x. P x ==> (0 < size x)) /\
    (!x1 x2. size x1 + size x2 <= size (combine x1 x2)) ==>
    (!x1 x2. P x1 ==> (size x2 < size (combine x1 x2)))'',
    ...)

prove (''!l1 l2. l1 <> [] ==> (LENGTH l2 < LENGTH (l1 ++ l2))'',
    some proof using ABSTRACT_LEMMA
)</pre>
```

#### Too clever tactics

- a common mistake is to use too clever tactics
  - intended to work on many (sub)goals
  - using TRY and other fancy trial and error mechanisms
  - intended to replace multiple simple, clear tactics
- typical case: a tactic containing TRY applied to many subgoals
- it is often hard to see why such tactics work
- if something goes wrong, they are hard to debug
- general advice: don't factor with tactics, instead use definitions and lemmata

# Too Clever Tactics Example I

### Bad Example Subgoals

```
prove (''!11 12. 11 <> [] ==> (LENGTH 12 < LENGTH (11 ++ 12))'',
Cases >> (
   REWRITE_TAC[listTheory.LENGTH, listTheory.LENGTH_APPEND] >>
   REPEAT STRIP_TAC >>
   DECIDE_TAC
))
```

### Alternative Good Example Subgoals II

```
prove (''!11 12. 11 <> [] ==> (LENGTH 12 < LENGTH (11 ++ 12))'',
Cases >> SIMP_TAC list_ss [])

prove (''!11 12. 11 <> [] ==> (LENGTH 12 < LENGTH (11 ++ 12))'',
Cases >| [
    REWRITE_TAC[],

    REWRITE_TAC[listTheory.LENGTH, listTheory.LENGTH_APPEND] >>
    REPEAT STRIP_TAC >>
    DECIDE_TAC
])
```

### Too Clever Tactics Example II

### Bad Example

```
val oadd_def = Define '(oadd (SOME n1) (SOME n2) = (SOME (n1 + n2))) /\
                       (oadd
                                               = NONE) :
val osub_def = Define '(osub (SOME n1) (SOME n2) = (SOME (n1 - n2))) /\
                       (osub
                                           = NONE)';
val omul_def = Define '(omul (SOME n1) (SOME n2) = (SOME (n1 * n2))) /\
                       (omul _
                                             = NONE)';
val onum NONE TAC =
 Cases_on 'o1' >> Cases_on 'o2' >>
 SIMP TAC std ss [oadd def. osub def. omul def]:
val oadd_NULL = prove (
  ''!o1 o2. (oadd o1 o2 = NONE) <=> (o1 = NONE) \/ (o2 = NONE)''.
 onum_NONE_TAC);
val osub_NULL = prove (
  ''!o1 o2. (osub o1 o2 = NONE) <=> (o1 = NONE) \/ (o2 = NONE)''.
 onum_NONE_TAC);
val omul NULL = prove (
  ''!o1 o2. (omul o1 o2 = NONE) <=> (o1 = NONE) \/ (o2 = NONE) '',
 onum_NONE_TAC);
```

### Too Clever Tactics Example II

#### Good Example

```
val obin_def = Define '(obin op (SOME n1) (SOME n2) = (SOME (op n1 n2))) /\
                       (obin
                                                    = NONE) :
val oadd_def = Define 'oadd = obin $+';
val osub_def = Define 'osub = obin $-';
val omul def = Define 'omul = obin $*':
val obin_NULL = prove (
  "'!op o1 o2. (obin op o1 o2 = NONE) <=> (o1 = NONE) \/ (o2 = NONE) \",
 Cases_on 'o1' >> Cases_on 'o2' >> SIMP_TAC std_ss [obin_def]);
val oadd_NULL = prove (
  ''!o1 o2. (oadd o1 o2 = NONE) <=> (o1 = NONE) \/ (o2 = NONE)'',
 REWRITE TAC[oadd def. obin NULL]):
val osub_NULL = prove (
  ''!o1 o2. (osub o1 o2 = NONE) <=> (o1 = NONE) \/ (o2 = NONE) '',
 REWRITE TAC[osub def. obin NULL]):
val omul_NULL = prove (
  ''!o1 o2. (omul o1 o2 = NONE) <=> (o1 = NONE) \/ (o2 = NONE)'',
 REWRITE_TAC[omul_def, obin_NULL]);
```

## Use many subgoals and lemmata

- often it is beneficial to use subgoals
  - they structure long proofs well
  - they help keeping the proof state clean
  - they mark clearly what one tries to proof and provide points where proofs can break sensibly
- general subgoals should often become lemmata
  - this improves reusability
  - proof scripts become shorter
  - proofs are disentangled

# Subgoal Example

• the following example is taken from exercise 5

```
First Version
```

# Subgoal Example II

### Subgoal Version

# Subgoal Example II

#### Lemma Version

## **Avoid Autogenerated Names**

- many HOL-tactics introduce new variable names
  - ▶ Induct
  - ► Cases
- the new names are often very artificial
- even worse, generated names might change in future
- proof scripts using autogenerated names are therefore
  - hard to read
  - potentially fragile
- therefore rename variables after they have been introduced
- HOL has multiple tactics supporting renaming
- most useful is rename1 'pat', it searches for pattern and renames vars accordingly

# Autogenerated Names Example

#### Bad Example

```
prove (''!l. 1 < LENGTH 1 ==> (?x1 x2 l'. l = x1::x2::l')'',
GEN_TAC >>
Cases_on '1' >> SIMP_TAC list_ss [] >>
Cases_on 't' >> SIMP_TAC list_ss [])
```

#### Good Example

```
prove (''!1. 1 < LENGTH 1 ==> (?x1 x2 l'. l = x1::x2::l')'',
GEN_TAC >>
Cases_on '1' >> SIMP_TAC list_ss [] >>
rename1 'LENGTH 12' >>
Cases_on '12' >> SIMP_TAC list_ss [])
```

#### Proof State before rename1

```
1 < SUC (LENGTH t) ==> ?x2 l'. t = x2::1'
```

#### Proof State after rename1

```
1 < SUC (LENGTH 12) ==> ?x2 1'. 12 = x2::1'
```
