

Principles of Wireless Sensor Networks

<https://www.kth.se/social/course/EL2745/>

Lecture 3
January 24, 2013

Carlo Fischione
Associate Professor of Sensor Networks
e-mail: carlofi@kth.se
<http://www.ee.kth.se/~carlofi/>

*KTH Royal Institute of Technology
Stockholm, Sweden*

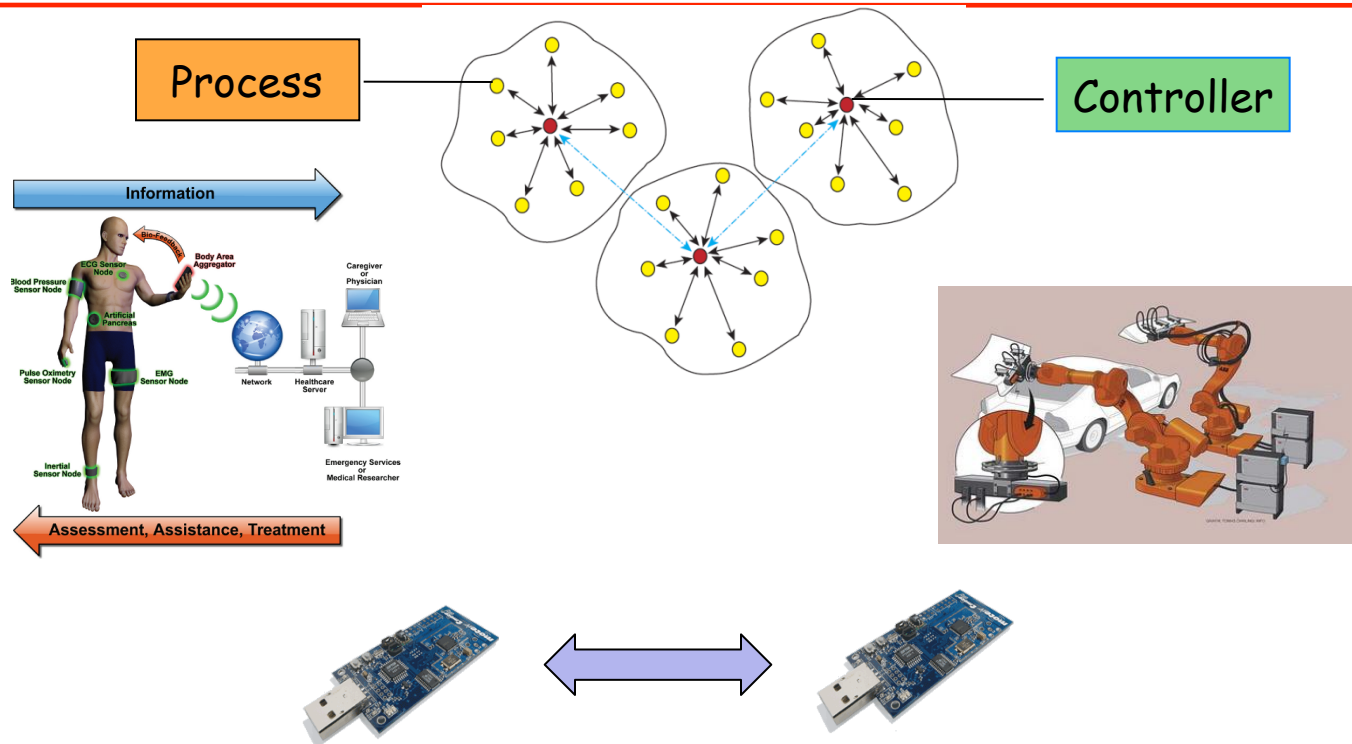

Course content

- Part 1
 - Lec 1: Introduction
 - Lec 2: Programming
- Part 2
 - Lec 3: The wireless channel
 - Lec 4: Physical layer
 - Lec 5: Mac layer
 - Lec 6: Routing
- Part 3
 - Lec 7: Distributed detection
 - Lec 8: Distributed estimation
 - Lec 9: Positioning and localization
 - Lec 10: Time synchronization
- Part 4
 - Lec 11: Networked control systems 1
 - Lec 12: Networked control systems 2
 - Lec 13: Summary and project presentations

- Suppose that a node has permission to transmit messages over wireless
- How the signals carrying the messages are treated by the wireless channel?

Today's learning goals

- What is the AWGN channel?
- How the channel attenuates (fades) the transmit power?
- What is the slow fading?
- What is the fast fading?

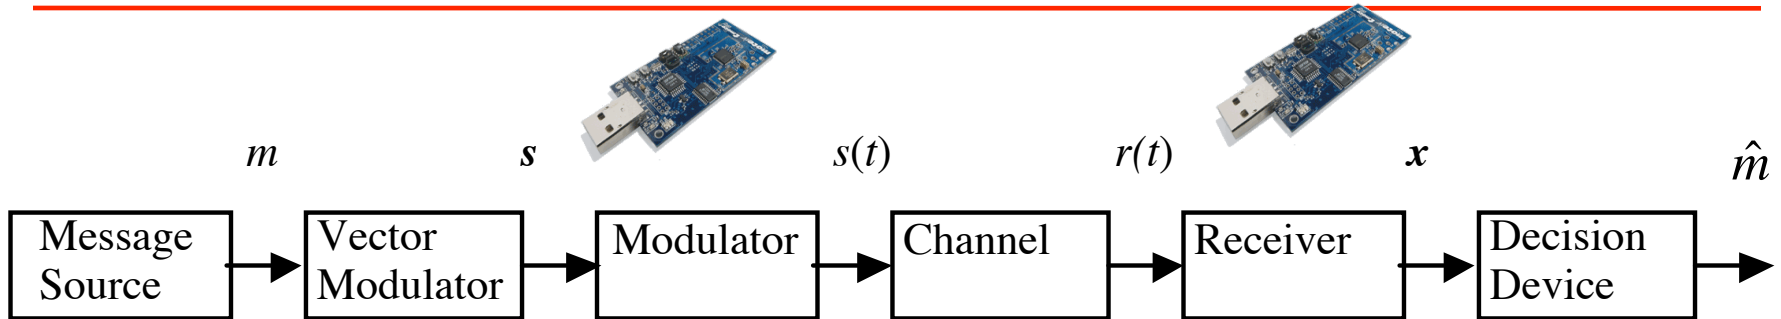

Today's lecture

- **Additive white Gaussian channel**
- The wireless channel fading models
- The Gilbert-Elliott model

Digital communications over wireless channels

m = source message, e.g., video, sounds, temperature

s = vector “quantized” source

$s(t)$ = modulated signal transmitter over the wireless channel

$r(t)$ = received signal

x = demodulated signal

\hat{m} = decoded signal

AWGN wireless channels

AWGN channel: the transmitted signal is received together with an Additive White Gaussian Noise

$$r(t) = s(t) + n_0(t)$$

$$n_0(t) \in N \left(0, \sigma^2 = \frac{N_0}{2T_s} \right)$$

Example: binary phase shift keying modulation

- To fix ideas, let us consider a basic modulation format: BPSK

$$s(t) = \begin{cases} \cos(2\pi f_c t) & \text{if bit 0 ,} \\ \cos(2\pi f_c t + \pi) = -\cos(2\pi f_c t) & \text{if bit 1.} \end{cases}$$

- f_c = carrier frequency over which the signal is transmitted
- f_c is around 2.4GHz for many low data rate and low power WSNs
- The presence of AWGN noise can determine an erroneous detection of the signal. See next lecture.

More real wireless channels

- In AWGN channels, the transmitted signal $s(t)$ is received corrupted by additive noise
- In real wireless channels it is also multiplicatively attenuated

$$r(t) = \sqrt{A}s(t) + n_0(t)$$

- The power of $s(t)$
$$P_t = \int_{t_0}^{t_0+T_s} s^2(t) dt$$

which, due to antennas and wireless channel, is attenuated by A

- The received power is

$$P_r = \int_{t_0}^{t_0+T_s} r^2(t) dt$$

- Let's see how P_r can be modeled

A little warning...

- The wireless channel behavior depends on the carrier frequency
- What we present below is for carrier frequencies around 2.4GHz, the typical for low data rate WSNs

Today's lecture

- Additive white Gaussian channel
- **The wireless channel fading models**
 - Path-loss
 - Slow fading
 - Fast fading
- The Gilbert-Elliott model

The wireless channel

- Communication channels are described by the impulse response

$$r(t) = s(t) \otimes h(t, \tau) = \int_{-\infty}^{+\infty} s(z)h(t, \tau - z)dz$$

$$P_t = \int_{t_0}^{t_0+T_s} s^2(t)dt$$

transmitted radio power over a time T_s

$$P_r = \int_{t_0}^{t_0+T_s} r^2(t)dt$$

received radio power (no additive noise)

The free space wireless channel

$$r(t) = \sqrt{A}s(t) + n_0(t)$$

$$\begin{aligned} P_r &= P_t G_t(\theta_t, \psi_t) G_r(\theta_r, \psi_r) c \\ &= P_t A \end{aligned}$$

$$G(\theta_t, \psi_t) \quad \text{antenna gain}$$

$$c = \frac{\lambda^2}{(4\pi r)^2} \bar{P} \bar{L} \cdot z \cdot y \quad \text{channel attenuation}$$

$$\lambda = \frac{v}{f_c} \quad \text{wavelength}$$

$$r \quad \text{distance between transmitter and receiver}$$

The carrier frequency affects the attenuations

The antenna

- The antenna determines the attenuations of the transmitted signals
- Let's see how

Antennas

- Antennas are transducers to transmit and receive radio signals
- Variable currents within antenna conductors induce radiation of electromagnetic waves
- Efficiency of energy capture to a receiver depends on
 1. the antenna geometry
 2. how impedance is matched between the antenna and the medium and between the antenna and the electronics
- Due to the reciprocity between transmission and reception, an antenna that is efficient in transmission is also efficient in reception

Antenna's radiation diagram

- Antennas are designed for shaping the pattern of reception or transmission
- Transmit power may have increased gains in particular directions

Antenna's figure of merit

Efficiency: the fraction of input energy that is radiated. By reciprocity, the fraction of incident radiation that is captured

Gain: the ratio of the intensity in the pattern to that of an isotropic antenna

Beamwidth: the angle between the 3 dB points of the main antenna lobe (set of angles with largest intensity).

Sidelobe suppression: the ratio of the peak intensity to the intensity of the largest sidelobe

The environment in which the antennas operates — the packaging of the radio receiver, and the presence of nearby conductive entities (e.g., people) can alter the antenna efficiency and beam pattern

The signal to noise ratio, SNR

- The antennas and wireless channel attenuates and distorts the transmitted radio power

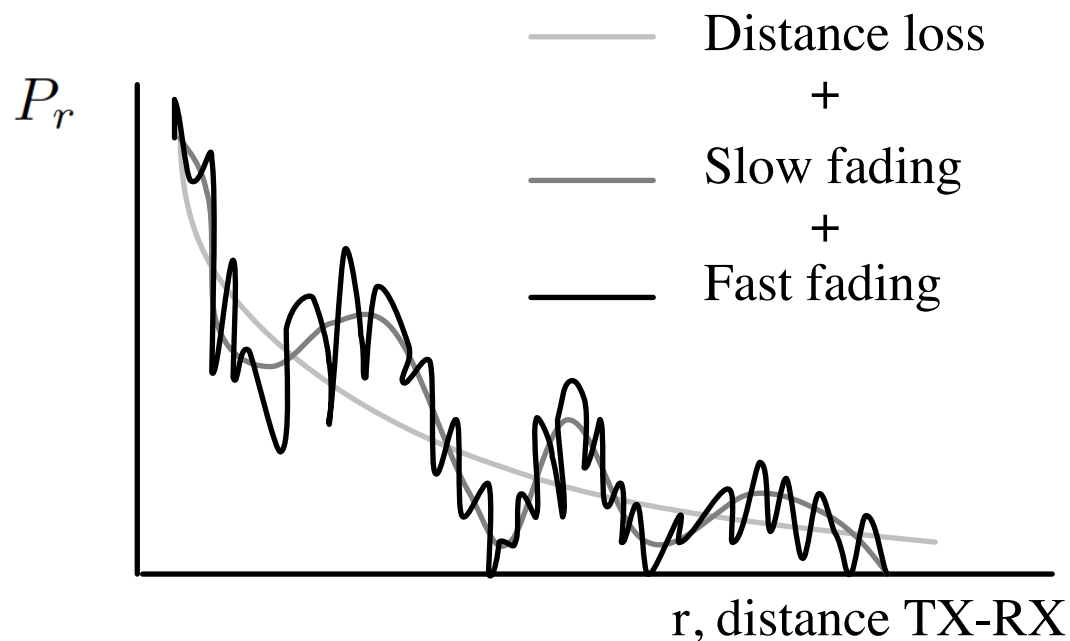

$$P_r = P_t G_t(\theta_t, \psi_t) G_r(\theta_r, \psi_r) \frac{\lambda^2}{(4\pi r)^2} \bar{P} \bar{L} \cdot y \cdot z$$

- The signal to noise ratio at the receiver is defined as

$$\text{SNR} = \frac{P_r}{N_0}$$

- For a fixed SNR,
 1. quadrupling the transmitted radio power doubles the range
 2. decreasing the carrier frequency of two will double the range

Channel attenuation vs distance

$$P_r = P_t G_t(\theta_t, \psi_t) G_r(\theta_r, \psi_r) \frac{\lambda^2}{(4\pi r)^2} \bar{P} \bar{L} \cdot z \cdot y$$

$$P_r = P_t G_t(\theta_t, \psi_t) G_r(\theta_r, \psi_r) \frac{\lambda^2}{(4\pi r)^2} \bar{P}L \cdot z \cdot y$$

- The path loss power depends on the distance transmitter receiver

$$PL = \frac{\lambda^2}{(4\pi r)^2} \bar{P}L$$

- The dB of the path loss power is often called Received Signal Strength (RSS) and provided by TelosB motes as RSSI, for indoor scenarios is

$$PL_{dB} = 10 \log_{10} PL = PL(d_0) - 10n_{SF} \log \left(\frac{r}{r_0} \right) - FAF - \sum_j PAF_j$$

path loss exponent

floor attenuation factor

path attenuation factor per obstacle within a room

Typical figures of path loss

Material	Loss (dB)
Aluminum siding	20
Foil insulation	4
Concrete block wall	8–20
One floor	10–30
One floor and one wall	40–50
Right-angle corner in corridor	10–15

Shadow fading

$$P_r = P_t G_t(\theta_t, \psi_t) G_r(\theta_r, \psi_r) \frac{\lambda^2}{(4\pi r)^2} \bar{P}L \cdot z \cdot y$$

$$y = e^{\frac{x}{10}}$$

$$X = N(\mu, \sigma^2)$$

The shadow fading often follows a lognormal probability distribution function

The fast fading channel attenuation

$$P_r = P_t G_t(\theta_t, \psi_t) G_r(\theta_r, \psi_r) \frac{\lambda^2}{(4\pi r)^2} \bar{P}L \cdot \textcolor{yellow}{z} \cdot y$$

- Fast fading is due to multi-path propagation
- For physical reasons, the square root of the fast fading can follow some probability distributions, such as Rayleigh, Rice, Nakagami...

Rayleigh fast fading

$$P_r = P_t G_t(\theta_t, \psi_t) G_r(\theta_r, \psi_r) \frac{\lambda^2}{(4\pi r)^2} \bar{P} \bar{L} \cdot z \cdot y$$

$$x^2 \triangleq z$$

$$f(x) = \frac{x}{\sigma^2} e^{-\frac{x^2}{2\sigma^2}}$$

- Fast fading may follow a Rayleigh distribution (if x is a Rayleigh random variable, z is an exponential random variable)

Multi-path Rayleigh fading

- The channel impulse response may spread the transmitted signal over time due to multiple reflectors

$$h(t, \tau) = \sqrt{G_t G_r P L y} \sum_i \alpha_i(t) e^{j\theta_i(t)} \delta(\tau - \tau_i(t))$$

Diagram illustrating the components of the channel impulse response equation:

- $\alpha_i(t)$: random variable with Rayleigh distribution
- $e^{j\theta_i(t)}$: imaginary number (random variable with uniform distribution)
- $\tau_i(t)$: delay of path i

$$\sqrt{z_i} \triangleq |\alpha_i(t) e^{j\theta_i(t)}| = \alpha_i(t)$$

Typical figures of fading

Environment	Distance exponent	Shadowing model	Multipath model
Free space	2	None	None
Urban cellular	2.7–3.5	Lognormal $\sigma = 8\text{--}9$ dB	Rayleigh or Rice
Shadowed urban cellular	3–5	Lognormal $\sigma = 8\text{--}9$ dB	Rayleigh
In building line of sight	1.6–1.8	None	Rice or lognormal
Obstructed in office building	4–6	Site-specific	Rayleigh or lognormal
Obstructed in factories	2–3	Site-specific	Lognormal
Satellite	2	Site-specific	Rice

Today's lecture

- Additive white Gaussian channel
- The wireless channel fading models
 - Path-loss
 - Slow fading
 - Fast fading
- **The Gilbert-Elliot model**

Gilbert-Elliot model

- It is a simple way to describe the behavior of the wireless channel in two states: Bad and Good

$$\pi_B + \pi_G = 1$$

$$\pi_G = (1 - p)\pi_G + r\pi_B$$

- π_B probability of bad state
- π_G probability of good state
- p probability to go from the good state to the bad
- r probability to go from the bad state to the good

Conclusions

Application
Presentation
Session
Transport
Routing
MAC
Phy

- We studied the wireless channel attenuates the transmit power
 - AWGN
 - Path loss
 - Slow fading
 - Fast fading
- Next lecture, we study the probability of erroneously decoding bits

Project

- The project is a 10-15 pages single column written report
- Must contain experimental results of your proposal
- Time line:
 1. Jan 21: every group communicates to carlofi@kth.se the preferences on the topic
 2. Jan 25: Carlo sends out the study material with detailed instructions
 3. Feb 4: every group e-mails to carlofi@kth.se the proposal for report table of content
 4. Feb 5: Carlo sends feedback on the proposal
 5. Feb 6: The groups start working on the writing and experiments
 6. Feb 6-Mar 4: groups work and ask feedback if needed to the teaching assistants and Carlo
 7. Feb 28: peer-review of the project report by two other groups
 8. March 4: every group gives a 10 minutes presentation on the project and submits the final project report
