PROBLEM 1

Calculate the gradient of the following scalar field:

$$\phi(x, y) = e^{-(x^2 + y^2)}$$

- (a) What is the direction of the maximum increase in point P=(-1,1)?
- (b) What is the maximum increase in point P=(-1,1)?

SOLUTION

- (a) The direction of the maximum increase is the direction of the gradient (*theorem 1*)

$$\text{grad}\phi = \left(\frac{\partial\phi}{\partial x}, \frac{\partial\phi}{\partial y} \right) = \left(-2xe^{-(x^2+y^2)}, -2ye^{-(x^2+y^2)} \right)$$

In P we have: $\text{grad}\phi = -2e^{-((-1)^2+1^2)} (-1,1) = -2e^{-2} (-1,1)$

The direction is: $\hat{d} = \frac{(1,-1)}{\sqrt{2}}$

- (b) The maximum increase in P is the absolute value of the gradient in P (*theorem 1*)

$$|\text{grad}\phi| = |-2e^{-2} (-1,1)| = 2e^{-2} \sqrt{2}$$

PROBLEM 2

The scalar fields f , g , h are given by:

$$f(\vec{r}) = 2xy - y^2z^2 + 2xz$$

$$g(\vec{r}) = x^3y + y^3z - xz^3$$

$$h(\vec{r}) = x^3y^2z + x^2yz^3 + xy^3z^2$$

- (a) Calculate the direction \hat{n} for which the directional derivative of f and g in the point $P(-1,0,1)$ is zero
- (b) Calculate the directional derivative of h in P along the direction \hat{n} $P(-1,0,1)$ is zero

SOLUTION

- (a) The directional derivative of the scalar field ϕ in the direction \hat{n} is:

$$\frac{d\phi}{ds} = \text{grad}\phi \cdot \hat{n}$$

Therefore, we need to find the direction \hat{n} for which:

$$\begin{cases} \text{grad}(f) \cdot \hat{n} = 0 \\ \text{grad}(g) \cdot \hat{n} = 0 \end{cases}$$

Let's calculate the gradient of f and g:

$$\text{grad } f = (2y + 2z, 2x - 2yz^2, -2y^2z + 2x)$$

$$\text{grad } g = (3x^2y - z^3, x^3 + 3y^2z, y^3 - 3xz^2)$$

In the point P=(-1,0,1) the gradients are:

$$(\text{grad } f)_P = (2, -2, -2)$$

$$(\text{grad } g)_P = (-1, -1, 3)$$

If $\hat{n} = (a, b, c)$ we obtain:

$$(\text{grad } f)_P \cdot \hat{n} = (2, -2, -2) \cdot (a, b, c) = 0$$

$$(\text{grad } g)_P \cdot \hat{n} = (-1, -1, 3) \cdot (a, b, c) = 0$$

$$\left. \begin{array}{l} a - b - c = 0 \\ a + b - 3c = 0 \end{array} \right\} \Rightarrow \begin{cases} a = 2c \\ b = c \end{cases}$$

Therefore: $\hat{n} = (2c, c, c)$

Normalizing:

$$\hat{n} = \frac{(2, 1, 1)}{\sqrt{6}}$$

(b) The directional derivative of the h in the direction \hat{n} in the point P is:

$$\left(\frac{dh}{ds} \right)_P = (\text{grad}h)_P \cdot \hat{n} = (0, 1, 0) \cdot \frac{(2, 1, 1)}{\sqrt{6}} = \frac{1}{\sqrt{6}}$$

PROBLEM 3

(A) Show a simple parametric description $\vec{r} = \vec{r}(u)$ for the curve:

$$\left\{ \begin{array}{l} 4x - y^2 = 0 \\ x^2 + y^2 - z = 0 \end{array} \right. \quad (1)$$

$$\quad (2)$$

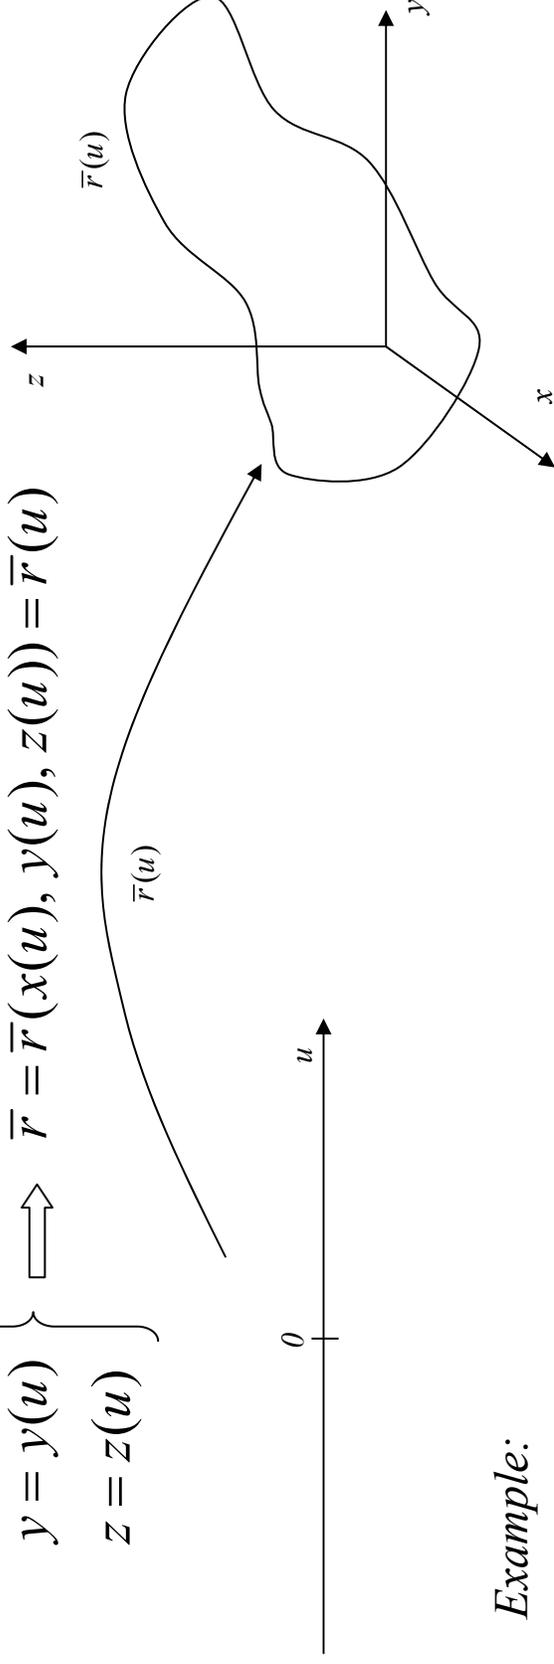

From the point $(0,0,0)$ to the point $(1,2,5)$

(B) Calculate the vector tangent to the point $\left(\frac{1}{4}, 1, \frac{17}{16} \right)$

SOLUTION (point A)

A “parameterization” means that we have to introduce a new variable (u for example). The “old” variables x , y , and z will be dependent on u .

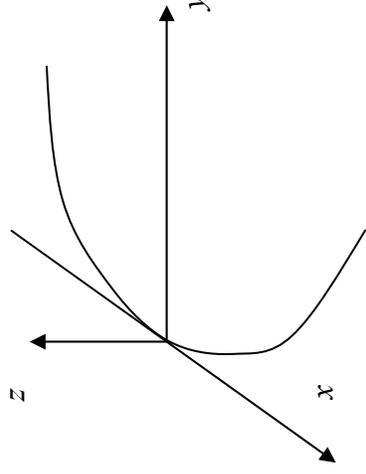

$$\left. \begin{array}{l} x = x(u) \\ y = y(u) \\ z = z(u) \end{array} \right\} \Rightarrow \bar{\mathbf{r}} = \bar{\mathbf{r}}(x(u), y(u), z(u)) = \bar{\mathbf{r}}(u)$$

Example:

$$\left. \begin{array}{l} x = u \\ y = u^2 \\ z = 0 \end{array} \right\} \Rightarrow \bar{\mathbf{r}}(u) = (u, u^2, 0)$$

A parabola located in the xy-plane

SOLUTION *(point A)*

$$4x - y^2 = 0 \quad (1)$$

$$x^2 + y^2 - z = 0 \quad (2)$$

From the point $(0,0,0)$ to the point $(1,2,5)$

For example, we can choose: $u=y$

$$\text{From equation (1)} \Rightarrow u^2 = 4x \Rightarrow x = \frac{u^2}{4}$$

$$\text{From equation (2)} \Rightarrow z = x^2 + y^2 = \frac{u^4}{16} + u^2$$

$$\text{So we obtain: } \bar{r}(u) = \left(\frac{u^2}{4}, u, \frac{u^4}{16} + u^2 \right)$$

From the point $(0,0,0)$ to the point $(1,2,5)$

$$(0,0,0) \Rightarrow u=0$$

$$(1,2,5) \Rightarrow u=2$$

The curve is:

$$\bar{r}(u) = \left(\frac{u^2}{4}, u, \frac{u^4}{16} + u^2 \right)$$
$$u: 0 \rightarrow 2$$

SOLUTION (point B)

The tangent in a point is the value of the derivative (calculated in the parameter u) in that point.

$$\bar{t} = \frac{d\bar{r}}{du} = \left(\frac{2u}{4}, 1, \frac{4u^3}{16} + 2u \right) = \left(\frac{u}{2}, 1, \frac{u^3}{4} + 2u \right)$$

The tangent has to be calculated in the point $\left(\frac{1}{4}, 1, \frac{17}{16} \right)$

since $u=y$, we have $u=1$

Therefore:

$$\bar{t} = \left(\frac{1}{2}, 1, \frac{1}{4} + 2 \right) = \left(\frac{1}{2}, 1, \frac{9}{4} \right)$$

PROBLEM 4

Consider the following surface:

$$x^2 - 2y^2 - 2z = 0 \quad (1)$$

Calculate:

- (A) The equations of the normal line to the surface in the point $P=(2,1,1)$
- (B) The equation of the tangent plane to the surface in the point P

SOLUTION (point A)

A normal line is a line that intersects the surface in the point. The direction of the line is perpendicular to the surface.

How to calculate the direction perpendicular to a surface?

Theorem 3: The gradient of a scalar field $\phi(x,y,z)$ in the point P is orthogonal to the level surface $\phi=c$ in P.

Consider the level surface $\phi = x^2 - 2y^2 - 2z = 0$

The normal line is perpendicular to the gradient

$$\text{grad}\phi = \left(\frac{\partial\phi}{\partial x}, \frac{\partial\phi}{\partial y}, \frac{\partial\phi}{\partial z} \right) = (2x, -4y, -2)$$

$$\text{In } P=(2,1,1) \quad \text{grad}\phi = (4, -4, -2)$$

The normal line can be written as: $\vec{n}_P = (4, -4, -2)$

SOLUTION (point B)

A tangent plane is a plane that is parallel to the surface in the point.

From “basic” geometry, given a vector $\vec{v} = (A, B, C)$

Then the plane $Ax + By + Cz + D = 0$ is perpendicular to \vec{v}

Therefore, using $\vec{v} = \vec{n}_P = (4, -4, -2)$

we have that the plane $4x - 4y - 2z + D = 0$ is perpendicular to \vec{n}_P

D is chosen in order that the plane passes through the point $P = (2, 1, 1)$:

$$4 \cdot 2 - 4 \cdot 1 - 2 \cdot 1 + D = 0 \quad \Rightarrow \quad D = -2$$

$2x - 2y - z - 1 = 0$ passes through P and is tangent to the surface
