- ▶ Consider installing a **WAMP/LAMP/MAMP pack**.
  - ▶ The first letter is you operating system (**W**indows, **L**inux or **M**acOS).
  - ▶ The other letters means **A**ppache, **M**ySQL and **P**HP. These together form a **complete web server**.
  - ▶ **EasyPHP** , <http://www.easyphp.org/>, is a WAMP pack that is **easy to install**.

[Introduction](#)[Types, Operators and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# Syntax

- ▶ A PHP file can contain both PHP and HTML.

# Syntax

- ▶ A PHP file can contain both PHP and HTML.
- ▶ HTML is passed to the browser, PHP is executed on the server, and the **resulting output is passed** to the browser.

[Introduction](#)[Types, Operators  
and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# Syntax

- ▶ A PHP file can contain both PHP and HTML.
- ▶ HTML is passed to the browser, PHP is executed on the server, and the **resulting output is passed** to the browser.
- ▶ PHP code is embedded between **<?php** and **?>** tags.
  - ▶ You might want to **omit the closing tag** since it produces a space in the output.

[Introduction](#)[Types, Operators  
and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# The First Example

```
<!DOCTYPE html>
<html>
  <head>
    <meta charset="UTF-8">
    <title></title>
  </head>
  <body>
    <h1>
      <?php
        echo 'Mixing PHP and'
        . ' HTML in the same '
        . 'file this way gives '
        . 'bad cohesion. TRY TO'
        . ' AVOID THAT!';
      ?>
    </h1>
  </body>
</html>
```

[Introduction](#)[Types, Operators  
and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# Accessing PHP Files

- ▶ A PHP file is accessed with a HTTP request with a **matching URL**, just like a HTML file is accessed,  
`http://myserver.se/path/to/thephpfile.php`

[Introduction](#)[Types, Operators  
and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# Accessing PHP Files

- ▶ A PHP file is accessed with a HTTP request with a **matching URL**, just like a HTML file is accessed,  
`http://myserver.se/path/to/thephpfile.php`
- ▶ Execution just **starts from the beginning** of the specified PHP file, there is nothing like a main method.

[Introduction](#)[Types, Operators and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# Accessing PHP Files (Cont'd)

- ▶ To call code in other PHP files, it is necessary to **include** those files.

# Accessing PHP Files (Cont'd)

- ▶ To call code in other PHP files, it is necessary to **include** those files.
- ▶ Files are included with the **include construct**, `include anotherfile.php;`.

[Introduction](#)[Types, Operators and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# Accessing PHP Files (Cont'd)

- ▶ To call code in other PHP files, it is necessary to **include** those files.
- ▶ Files are included with the **include construct**, `include anotherfile.php;`.
- ▶ The interpreter will look for files at the specified **file path**, at specified **include paths**, in the **calling file's directory**, and in the current **working directory**.

[Introduction](#)[Types, Operators  
and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# Accessing PHP Files (Cont'd')

- ▶ **include** will emit a **warning** if it cannot find a file. There is also the **require** construct which works like **include** but emits a **fatal error** if the specified file is not found.

[Introduction](#)[Types, Operators  
and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# Accessing PHP Files (Cont'd')

- ▶ **include** will emit a **warning** if it cannot find a file. There is also the **require** construct which works like **include** but emits a **fatal error** if the specified file is not found.
- ▶ **include\_once** and **require\_once** works like **include** and **require**, except that the same file is **included only once** even if it is specified in multiple inclusion statements.

[Introduction](#)[Types, Operators and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# Naming Conventions

- ▶ There is no globally accepted naming convention as in for example Java, but the following is quite common.

[Introduction](#)[Types, Operators  
and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# Naming Conventions

- ▶ There is no globally accepted naming convention as in for example Java, but the following is quite common.
- ▶ **Class and interface** names are written in PascalCase, **MyFirstClass**

[Introduction](#)[Types, Operators and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# Naming Conventions

- ▶ There is no globally accepted naming convention as in for example Java, but the following is quite common.
- ▶ **Class and interface** names are written in PascalCase, **MyFirstClass**
- ▶ **Method** names are written in camelCase, **myFirstMethod**

# Comments

[Introduction](#)[Types, Operators  
and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

There are three different kinds of **comments**:

```
// Single line comment
```

```
# Single line comment
```

```
/*  
    Multiple line comment  
*/
```

# Identifiers

- ▶ A valid identifier starts with a letter or underscore, followed by any number of letters, numbers, or underscores.

[Introduction](#)[Types, Operators  
and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# Identifiers

- ▶ A valid identifier starts with a letter or underscore, followed by any number of letters, numbers, or underscores.
- ▶ Identifiers are **case sensitive**.

[Introduction](#)[Types, Operators  
and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# Variables

- ▶ Variables are represented by a **dollar sign**, \$, followed by the **name** of the variable.

[Introduction](#)[Types, Operators  
and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# Variables

- ▶ Variables are represented by a **dollar sign**, \$, followed by the **name** of the variable.
- ▶ There are no variable declarations, PHP is **dynamically typed**.
  - ▶ A variable is created and assigned an appropriate type when it is **first used**, much the same way as in JavaScript.

[Introduction](#)[Types, Operators and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# Variables

- ▶ Variables are represented by a **dollar sign**, \$, followed by the **name** of the variable.
- ▶ There are no variable declarations, PHP is **dynamically typed**.
  - ▶ A variable is created and assigned an appropriate type when it is **first used**, much the same way as in JavaScript.
- ▶ A variable that has never been assigned a value is **unbound** and has the value **NULL**

[Introduction](#)[Types, Operators  
and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# Variables

and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# Cast (Explicit Conversion)

- ▶ Three ways to specify an explicit conversion.

```
(int)$total  
intval($total)  
settype($total, "integer")
```

[Introduction](#)[Types, Operators  
and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# Output

- ▶ Output from the PHP program is **included in the out stream** from server to browser.

# Output

- ▶ Output from the PHP program is **included in the out stream** from server to browser.
- ▶ There are three ways to generate output. The first two, **print** and **echo**, differ only in that **print** has a return value.

```
$what = "Hello";  
$who = "World!";  
echo $what . " " . $who;  
print($what . " " . $who);
```

[Introduction](#)[Types, Operators  
and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# Error Messages From Interpreter

- ▶ The **PHP interpreter's output**, for example exception reports, goes to the web server's log.

[Introduction](#)[Types, Operators  
and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# Error Messages From Interpreter

- ▶ The **PHP interpreter's output**, for example exception reports, goes to the web server's log.
- ▶ The **location of that log** depends on server and operating system.
  - ▶ On my Ubuntu/Apache platform, the log is in **`/var/log/apache2/error.log`**.

[Introduction](#)[Types, Operators  
and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# Error Messages From Interpreter

- ▶ The **PHP interpreter's output**, for example exception reports, goes to the web server's log.
- ▶ The **location of that log** depends on server and operating system.
  - ▶ On my Ubuntu/Apache platform, the log is in `/var/log/apache2/error.log`.
- ▶ It is **strongly recommended** to locate this **log** since that is where you will see if your PHP program crashed.

[Introduction](#)[Types, Operators and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# Error Messages From Interpreter

- ▶ The **PHP interpreter's output**, for example exception reports, goes to the web server's log.
- ▶ The **location of that log** depends on server and operating system.
  - ▶ On my Ubuntu/Apache platform, the log is in `/var/log/apache2/error.log`.
- ▶ It is **strongly recommended to locate this log** since that is where you will see if your PHP program crashed.
- ▶ Remember that PHP programs are not compiled. The only way to be **notified of coding errors** is through the above mentioned log.

[Introduction](#)[Types, Operators and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# Relational and Logical Operators

- ▶ The **relational operators** are the same as in JavaScript, including `===` and `!==`.

[Introduction](#)[Types, Operators  
and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# Relational and Logical Operators

[Introduction](#)[Types, Operators  
and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

- ▶ The **relational operators** are the same as in JavaScript, including `===` and `!==`.
- ▶ The **logical operators** comes in two flavors. The difference is that number one has higher precedence than assignment operators while number two has lower.
  1. **&&**, **!** and **||**
  2. **and**, **or** and **xor**

# Control Statements

- ▶ The following **control statements** behave as in Java, **if**, **else**, **else if**, **while**, **do-while**, **for**, **switch**, **break** and **continue**.

[Introduction](#)[Types, Operators  
and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# Control Statements

- ▶ The following [control statements](#) behave as in Java, **if**, **else**, **else if**, **while**, **do-while**, **for**, **switch**, **break** and **continue**.
- ▶ There is also the **foreach** statement which is different from Java. It will be [covered below](#), after arrays.

[Introduction](#)[Types, Operators  
and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# The Array Type

- ▶ Not like arrays of any other language.
- ▶ A PHP array is actually an ordered map.
  - ▶ A map is a type that associates values to keys.
  - ▶ Ordered means elements are located at indexes.

[Introduction](#)[Types, Operators  
and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# The Array Type

- ▶ Not like arrays of any other language.
- ▶ A PHP array is actually an ordered map.
  - ▶ A map is a type that associates values to keys.
  - ▶ Ordered means elements are located at indexes.
- ▶ This means arrays can be used for many different data structures, like lists and hash tables.

[Introduction](#)[Types, Operators  
and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# To Create an Array

- ▶ Arrays can be created with the **array()** **construct**, which takes comma-separated **key => value** pairs as arguments.

```
$my_array = array(  
    3      => "value1",  
    "key2" => 38  
)
```

[Introduction](#)[Types, Operators  
and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# To Create an Array

- ▶ Arrays can be created with the **array()** **construct**, which takes comma-separated **key => value** pairs as arguments.

```
$my_array = array(  
    3      => "value1",  
    "key2" => 38  
)
```

- ▶ Arrays can also be created with the **short array syntax**, **[]**

```
$my_array = [  
    3      => "value1",  
    "key2" => 38  
]
```

# Iterating Over Elements

- ▶ An array can be iterated with the **foreach** construct.

```
foreach ($arr as $value) {  
    echo("$value");  
}
```

```
foreach ($arr as $key => $value) {  
    echo "Key: $key, Value: $value; ";  
}
```

[Introduction](#)[Types, Operators  
and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# Iterating Over Elements (Cont'd)

- ▶ Also the **while** construct can be used.

```
while (list(, $value) = each($arr)) {  
    echo("$value");  
}
```

```
while (list($key, $value) = each($arr)) {  
    echo "Key: $key, Value: $value;";  
}
```

[Introduction](#)[Types, Operators  
and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# Iterating Over Elements (Cont'd)

- ▶ Also the **while** construct can be used.

```
while (list(, $value) = each($arr)) {

and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# Arguments

- ▶ Arguments are by default passed **by reference**.

[Introduction](#)[Types, Operators  
and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# Arguments

- ▶ Arguments are by default passed **by reference**.
- ▶ To pass **by value**, prepend an ampersand, **&**, to the argument.

```
function add_a_dot(&$string) {  
    $string .= ' .';  
}  
  
$str = 'My name is Olle';  
add_a_dot($str);  
echo $str;      // prints 'My name is Olle.'
```

[Introduction](#)[Types, Operators  
and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# Arguments

- ▶ Arguments are by default passed **by reference**.
- ▶ To pass **by value**, prepend an ampersand, **&**, to the argument.

```
function add_a_dot(&$string) {  
    $string .= ' .';  
}  
  
$str = 'My name is Olle';  
add_a_dot($str);  
echo $str;      // prints 'My name is Olle.'
```

- ▶ There can be default argument values.

```
function add_two($op1, $op2=2) {  
    return $op1 + $op2;  
}  
echo add_two(3); // prints '5'
```

[Introduction](#)[Types, Operators  
and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# Variable-Length Argument List

- ▶ A variable-length argument list is implemented with the functions

**func\_num\_args()**,  
**func\_get\_arg()** and  
**func\_get\_args()**.

```
function sum() {  
    $acc = 0;  
    foreach (func_get_args() as $n) {  
        $acc += $n;  
    }  
    return $acc;  
}  
  
echo sum(1, 2, 3, 4); // prints '10'
```

[Introduction](#)[Types, Operators  
and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# Variable Function

A **variable function** is a function whose name is the **value of a variable**. Variables with appended parentheses are treated as variable functions.

```
function foo() {  
    echo "In foo";  
}  
  
function bar() {  
    echo "In bar";  
}  
  
$func = 'foo';  
$func();           // prints 'In foo'  
  
$func = 'bar';  
$func();           // prints 'In bar'
```

[Introduction](#)[Types, Operators  
and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# Anonymous Functions and Closures

- ▶ **Anonymous functions** and **closures** behaves very much as in JavaScript.

```
function outer($param) {  
    return function() use ($param) {  
        echo "Inner got '$param'";  
    };  
}  
  
$func = outer('Hi!');  
echo $func(); //prints Inner got 'Hi!'
```

[Introduction](#)[Types, Operators  
and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# Anonymous Functions and Closures

- ▶ **Anonymous functions** and **closures** behaves very much as in JavaScript.

```
function outer($param) {  
    return function() use ($param) {  
        echo "Inner got '$param'";  
    };  
}  
  
$func = outer('Hi!');  
echo $func(); //prints Inner got 'Hi!'
```

- ▶ As can be seen above, **closures are defined** with the construct **use**.

```
▶ class SimpleClass {  
    private $var = 'a default value';  
  
    public function displayVar() {  
        echo $this->var;  
    }  
}  
  
$instance = new SimpleClass();  
echo $instance->displayVar();
```

- ▶ Note 1: The syntax for **method call** is **→**
- ▶ Note 2: It is not possible to specify a visibility for the class itself, **all classes are public**.

and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# Constructors

- ▶ Constructors work the same ways as in Java, but they are always called **\_\_construct**.

```
▶ class SimpleClass {  
    private $var;  
  
    public function __construct($var) {  
        $this->var = $var;  
    }  
}
```

- ▶ Note 1: Also the **this** variable is prefixed with **\$**

[Introduction](#)[Types, Operators  
and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# Constructors

- ▶ Constructors work the same ways as in Java, but they are always called **\_\_construct**.

```
class SimpleClass {  
    private $var;  
  
    public function __construct($var) {  
        $this->var = $var;  
    }  
}
```

- ▶ Note 1: Also the **this** variable is prefixed with **\$**
- ▶ Note 2: There is no overloading, there can be **only one constructor** per class.

[Introduction](#)[Types, Operators  
and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# Destructors

- ▶ Unlike Java, the destructor is called when the **last reference** to the object is removed.

[Introduction](#)[Types, Operators  
and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# Destructors

- ▶ Unlike Java, the destructor is called when the **last reference** to the object is removed.
- ▶ The destructor is called **\_\_destruct**

[Introduction](#)[Types, Operators  
and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# Destructors

- ▶ Unlike Java, the destructor is called when the **last reference** to the object is removed.
- ▶ The destructor is called **\_\_destruct**

```
class SimpleClass {  
    public function __destruct() {  
        echo 'running destructor';  
    }  
}  
  
$instance = new SimpleClass();
```

[Introduction](#)[Types, Operators  
and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# Destructors

- ▶ Unlike Java, the destructor is called when the **last reference** to the object is removed.
- ▶ The destructor is called **\_\_destruct**

```
class SimpleClass {  
    public function __destruct() {  
        echo 'running destructor';  
    }  
}  
  
$instance = new SimpleClass();
```

- ▶ The code above prints **running destructor** since the last reference to the object is removed when program ends.

[Introduction](#)[Types, Operators  
and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# Destructors

- ▶ Unlike Java, the destructor is called when the **last reference** to the object is removed.
- ▶ The destructor is called **\_\_destruct**
- ▶

```
class SimpleClass {  
    public function __destruct() {  
        echo 'running destructor';  
    }  
}  
  
$instance = new SimpleClass();
```
- ▶ The code above prints **running destructor** since the last reference to the object is removed when program ends.
- ▶ Note that the destructor can **not take any parameters**.

[Introduction](#)[Types, Operators  
and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# self and static

**self** is resolved to the class where it is written, **static** is resolved to the called class.

```
class SuperClass {
    public static function whoAreYouSelf() {
        self::me();
    }

    public static function whoAreYouStatic() {
        static::me();
    }

    protected static function me() {
        echo "I am SuperClass";
    }
}

class SubClass extends SuperClass {
    protected static function me() {
        echo "I am SubClass";
    }
}
```

```
SubClass::whoAreYouSelf();    //prints 'I am SuperClass'
```

```
SubClass::whoAreYouStatic(); //prints 'I am SubClass'
```

[Introduction](#)[Types, Operators  
and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# The Scope Resolution Operator and Late Static Binding

- ▶ The **double colon** used on the previous slide is called the **scope resolution operator**.

[Introduction](#)[Types, Operators and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# The Scope Resolution Operator and Late Static Binding

- ▶ The **double colon** used on the previous slide is called the **scope resolution operator**.
- ▶ Used to specify **which class to use**.

[Introduction](#)[Types, Operators and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# The Scope Resolution Operator and Late Static Binding

- ▶ The **double colon** used on the previous slide is called the **scope resolution operator**.
- ▶ Used to specify **which class to use**.
- ▶ Using **static**, as illustrated on the previous slide, is **late static binding**, which means that the scope is the **called class**.

# Object Iteration

- ▶ It is possible to **iterate over fields** in an object, as if the object was an array.

[Introduction](#)[Types, Operators  
and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)[\) {](#)

# Object Iteration

- ▶ It is possible to **iterate over fields** in an object, as if the object was an array.
- ▶ Only **visible fields**, as specified by the visibility, will occur in the iteration.

```
class Person {  
    public $name;  
    public $phone;  
    public $address;  
  
    public function __construct($name, $phone, $address) {  
        $this->address = $address;  
        $this->phone = $phone;  
        $this->name = $name;  
    }  
}  
  
$stina = new Person("Stina", "1234567", "at home");  
foreach ($stina as $key => $value) {  
    echo "$key: $value";  
}
```

[Introduction](#)[Types, Operators  
and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# Comparing Objects

- ▶ The comparison operator, `==`, considers two object instances equal if they have the **same attributes and values**, and are instances of the **same class**.

[Introduction](#)[Types, Operators  
and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# Comparing Objects

- ▶ The comparison operator, `==`, considers two object instances equal if they have the **same attributes and values**, and are instances of the **same class**.
- ▶ The identity operator, `===`, considers instances to be equal only if they refer to the **same instance and same class**.

[Introduction](#)[Types, Operators  
and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# Object Serialization

- ▶ The **serialize** function returns a **string** containing a representation of any PHP value.

[Introduction](#)[Types, Operators  
and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# Object Serialization

- ▶ The **serialize** function returns a string containing a representation of any PHP value.
- ▶ The **unserialize** function recreates the original values.

[Introduction](#)[Types, Operators  
and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# Object Serialization

- ▶ The **serialize** function returns a **string** containing a representation of any PHP value.
- ▶ The **unserialize** function **recreates the original values**.
- ▶ Serializing an object will save **all variable values plus the class name** of that object.

[Introduction](#)[Types, Operators  
and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# Object Serialization

- ▶ The **serialize** function returns a **string** containing a representation of any PHP value.
- ▶ The **unserialize** function **recreates the original values**.
- ▶ Serializing an object will save **all variable values plus the class name** of that object.
- ▶ To unserialize an object, the **class definition** of that object needs to be present.

[Introduction](#)[Types, Operators  
and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# Object Serialization, Example

```
class Person {
    public $name;
    public $phone;
    public $address;

    public function __construct($name, $phone, $address) {
        $this->address = $address;
        $this->phone = $phone;
        $this->name = $name;
    }
}

$stina = new Person("Stina", "1234567", "at home");
$serialized = serialize($stina);
// prints O:6:"Person":3:{s:4:"name";s:5:"Stina";
//      s:5:"phone";s:7:"1234567";
//      s:7:"address";s:7:"at home";}
echo $serialized;

$someone = unserialize($serialized);
foreach ($someone as $key => $value) {
    echo "$key: $value"; //Same output as before serializing
}
```

# Namespaces

- ▶ **Namespaces** are used to structure the program, as packages are used in Java.

[Introduction](#)[Types, Operators  
and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# Namespaces

- ▶ **Namespaces** are used to structure the program, as packages are used in Java.
- ▶ A namespace does not affect visibility, there is **no package private** visibility.

[Introduction](#)[Types, Operators and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# Namespaces

- ▶ **Namespaces** are used to structure the program, as packages are used in Java.
- ▶ A namespace does not affect visibility, there is **no package private** visibility.
- ▶ Namespaces **define name spaces**, the same symbol (e.g., class) can exist in different namespaces.

[Introduction](#)[Types, Operators and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# Namespaces

- ▶ **Namespaces** are used to structure the program, as packages are used in Java.
- ▶ A namespace does not affect visibility, there is **no package private** visibility.
- ▶ Namespaces **define name spaces**, the same symbol (e.g., class) can exist in different namespaces.
- ▶ Namespaces also structure the program and thereby **improve cohesion**.
  - ▶ If, for example, the MVC architecture is used, there should be the namespaces **Model**, **View** and **Controller**.

[Introduction](#)[Types, Operators  
and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# Declaring Namespaces

Namespaces are declared with the **namespace** keyword, placed first in a file.

```
namespace Model;
```

```
namespace \MyProject\Model\Payment;
```

[Introduction](#)[Types, Operators  
and Expressions](#)[Arrays](#)[Functions](#)[Objects](#)[Namespaces](#)[Exception Handling](#)[PHPDoc](#)

# Importing Namespaces

- ▶ Namespaces are **imported** with the **use** keyword and aliased with **alias**.

# Writing PHPDoc

- For simple use cases, PHPDoc is **very much like Javadoc**.

```
/**
 * Creates a cache with the specified layout.
 *
 * @param \Csim\Model\CacheLayout $layout The layout
 *        of the cache that shall be created.
 * @return \Csim\Model\SimulationState The state of
 *        the newly created, empty, cahce.
 */
public function
    defineCache(\Csim\Model\CacheLayout $layout) {
    $this->cache = new \Csim\Model\Cache($layout);
    return $this->cache->getState();
}
```
